### Reconciling cosmic dipolar tensions with a gigaparsec void

Tingqi Cai, Qianhang Ding, Yi Wang

Recent observations indicate a  $4.9\sigma$  tension between the CMB and quasar dipoles. This tension challenges the cosmological principle. We propose that if we live in a gigaparsec scale void, the CMB and quasar dipolar tension can be reconciled. This is because we are unlikely to live at the center of the void. And a 15% offset from the center will impact the quasars and CMB differently in their dipolar anisotropies. As we consider a large and thick void, our setup can also ease the Hubble tension.

### Dipole Cosmology: The Copernican Paradigm Beyond FLRW

Chethan Krishnan, Ranjini Mondol, M. M. Sheikh-Jabbari

We introduce the *dipole cosmological principle*, the idea that the Universe is a maximally Copernican cosmology, compatible with a cosmic flow. It serves as the most symmetric paradigm that generalizes the FLRW ansatz, in light of the increasingly numerous (but still tentative) hints that have emerged in the last two decades for a non-kinematic component in the CMB dipole. Einstein equations in our "dipole cosmology" are still ordinary differential equations -- but instead of the two Friedmann equations, now we have four. The two new functions can be viewed as an anisotropic scale factor that breaks the isotropy group from  $SO(3)$  to  $U(1)$ , and a "tilt" that captures the cosmic flow velocity. The result is an axially isotropic, tilted Bianchi V/VII<sub>h</sub> cosmology. We assess the possibility of model building within the dipole cosmology paradigm, and discuss the dynamics of expansion rate, anisotropic shear and tilt, in various examples. A key observation is that the cosmic flow (tilt) can grow even while the anisotropy (shear) dies down. Remarkably, this can happen even in an era of late time acceleration.

# How to explain the inconsistency?

Before giving up the cosmological principle, can we explain it from the **perturbed FRW**?

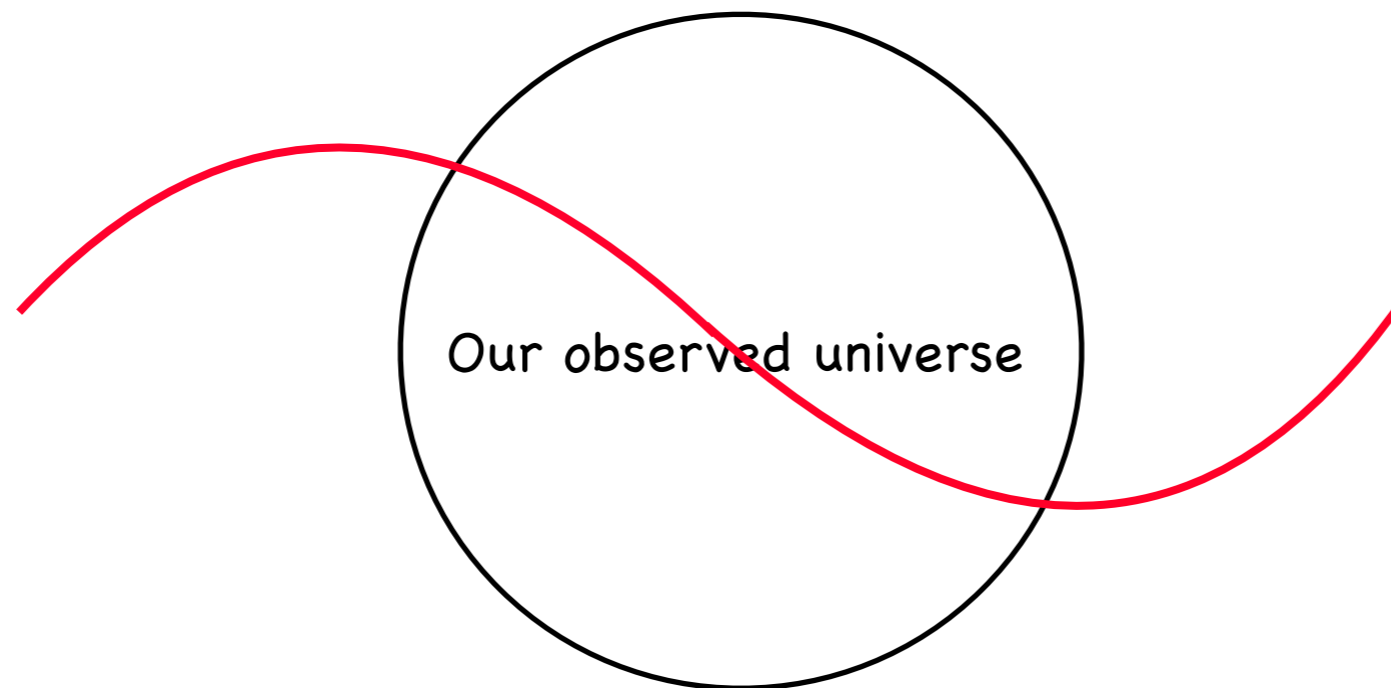

Anisotropies at CMB (commonly believed from the inflation)

# Perturbations at super horizon scale

Inflation  Perturbations at super horizon scale

If we are living in a large super horizon mode, there may be a dipole

## Dipole Anisotropy from an Entropy Gradient 1996'

David Langlois<sup>1,2</sup> and Tsvi Piran<sup>1</sup>

We can not observe this dipole from CMB if the perturbation is adiabatic

However, if there is entropy(isocurvature) mode at super horizon scale, an intrinsic dipole appears in CMB

# Adiabatic/curvature vs entropy/isocurvature perturbation

For radiation dominated universe

$$S = \frac{3}{4} \frac{\delta\rho_r}{\rho_r} - \frac{\delta\rho_m}{\rho_m}$$

Single field inflation only generates adiabatic perturbation

Thermal(for example, WIMP) dark matter only generates very tiny entropy perturbation

dark matter and radiation share same fluctuation

$$S = 0$$

$$S \neq 0$$

dark matter and radiation have different fluctuations

# Adiabatic/curvature vs entropy/isocurvature perturbation

The contribution of galaxy number counts, seems complicated

$$\begin{aligned}\Delta_{\mathcal{N}}(z_s, \hat{n}) = & \left(2 + \frac{\mathcal{H}'_s}{\mathcal{H}_s^2} + \frac{2-5s}{r_s \mathcal{H}_s} - f_{\text{evo}}\right) n_i v_o^i \\ & + b(z) \delta_{n,c} + (3 - f_{\text{evo}}) \mathcal{H}_s v_s + \Psi_s + n_i v_s^i + \frac{1}{\mathcal{H}_s} \left( \frac{d\Psi_s}{d\lambda_s} - \frac{d}{d\lambda_s} (n_i v_s^i) + \Psi'_s - \Phi'_s \right) \\ & + \left(5s + \frac{2-5s}{r_s \mathcal{H}_s} + \frac{\mathcal{H}'_s}{\mathcal{H}_s^2} - f_{\text{evo}}\right) \left( \Psi_s - n_i v_s^i + \int_0^{\lambda_s} d\lambda \frac{\partial}{\partial \eta} (\Psi - \Phi) \right) \\ & + (2 - 5s) \Phi_s - \frac{2-5s}{2r_s} \int_0^{\lambda_s} d\lambda \frac{r_s - r}{r} \Delta_{\Omega} (\Psi - \Phi) + \frac{2-5s}{r_s} \int_0^{\lambda_s} d\lambda (\Psi - \Phi),\end{aligned}$$

$$s(z) \equiv -\frac{2}{5} \frac{\partial \ln \mathcal{N}_s}{\partial \ln L}$$
$$f_{\text{evo}} \equiv -\frac{\partial \ln \mathcal{N}_s}{\partial \ln(1+z_s)}$$

**Galaxy number-count dipole and superhorizon fluctuations**

Guillem Domènech, Roya Mohayaee, Subodh P. Patil, Subir Sarkar

They all cancel at an order  $kr_{\text{dec}}$

Minimal contribution at an order of  $(kr_{\text{dec}})^3$

For  $kr_{\text{dec}} \ll 1$  no effect on galaxy number count dipole

# One solution to the cosmic dipole problem

CMB dipole  $D_1^{\text{CMB}} = (1.23357 \pm 0.00036) \times 10^{-3}$

$$n_i v_o^i = 369.82 \pm 0.11 \text{ km/s}$$

Galaxy number count dipole

$$d_{\mathcal{N}} = (15.54 \pm 1.7) \times 10^{-3}$$

$$n_i v_o^i = (2.66 \pm 0.29) \times 10^{-3} \Rightarrow 797 \pm 87 \text{ km/s}$$

If there is **intrinsic dipole** in CMB, it cancels part of kinematic dipole

$$d^{\text{CMB}} = d_{\text{kin}}^{\text{CMB}} + D_1^{\text{CMB}} = 1.23357 \times 10^{-3}$$

For single super-horizon mode  $k$ ,

$$D_1^{\text{CMB}} \sim 0.18 k r_{\text{dec}} S_{,1} > 8 \times 10^{-4}$$

a rather large  $S$  is needed

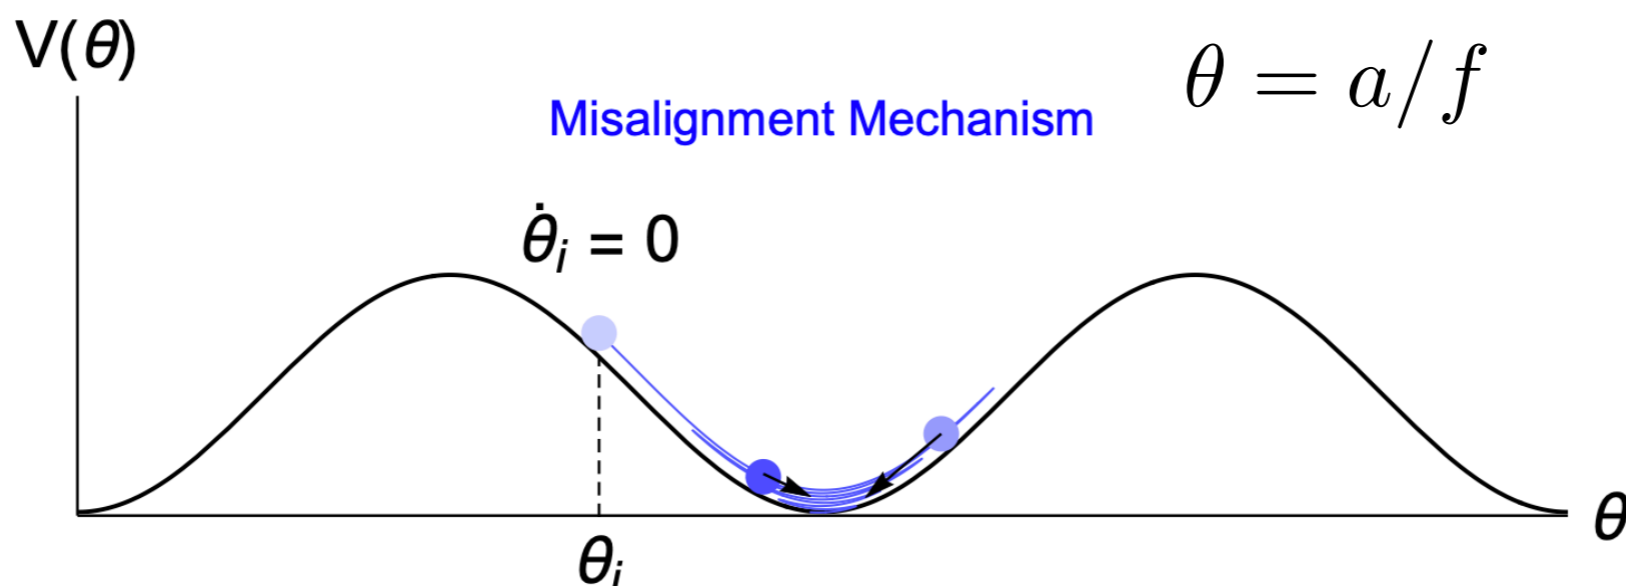

# What is the origin of the isocurvature/entropy mode?

Obviously thermal dark matter can not work

Axion dark matter is one of the candidate

$$V(\Phi) = \lambda(\Phi\Phi^\dagger - f^2/2)^2 \quad \Phi = \frac{1}{\sqrt{2}}\varphi \exp(i\frac{a}{f})$$

$$\rho = \frac{1}{2}m_a^2 f^2 \theta_0^2 \quad V = \Lambda^4(1 - \cos \frac{a}{f})$$

# Axion dark matter

During inflation

$$\rho = \frac{1}{2} m_a^2 f^2 \theta_0^2 \quad \delta\theta = \frac{H}{2\pi\varphi}$$

$$\delta\rho/\rho = \frac{H}{\pi\varphi\theta_0}$$

Limit on the large isocurvature from CMB for theta  $O(1)$

$$\frac{H^2}{\pi^2 f_a^2} < 10^{-10} \quad H/f_a < 10^{-5}$$

It is too small to explain the dipole problem by axion

# Axion dark matter

If the radial mode vary in the early universe(during inflation)

$$\mathcal{P}_S^{1/2} = \frac{H_{inf}}{\pi\varphi(k)\theta}$$

$\varphi$  from a small value around  $H$  to a large value  $f$

Potential

$$V(\Phi) = \lambda(\Phi\Phi^\dagger - f^2/2)^2$$

$$\Phi = \frac{1}{\sqrt{2}}\varphi \exp(i\frac{a}{f})$$

$$\delta\rho/\rho = \frac{H}{\pi\varphi}$$

initial phi should around H

# A model of large isocurvature

$$\ddot{\varphi} + 3H\dot{\varphi} + V'(\varphi) = 0$$

$$\lambda = 10^{-9}, 2 \times 10^{-9}, 4 \times 10^{-9}$$

Small lambda, longer stay at small value

# Axion model to explain dipole problem

Only two parameters

- (1) when to start?(super horizon size)
- (2) how long it takes?(lambda)

$$V(\Phi) = \lambda(\Phi\Phi^\dagger - f^2/2)^2 \quad 7 \times 10^{-10} < \lambda < 6.6 \times 10^{-5}$$

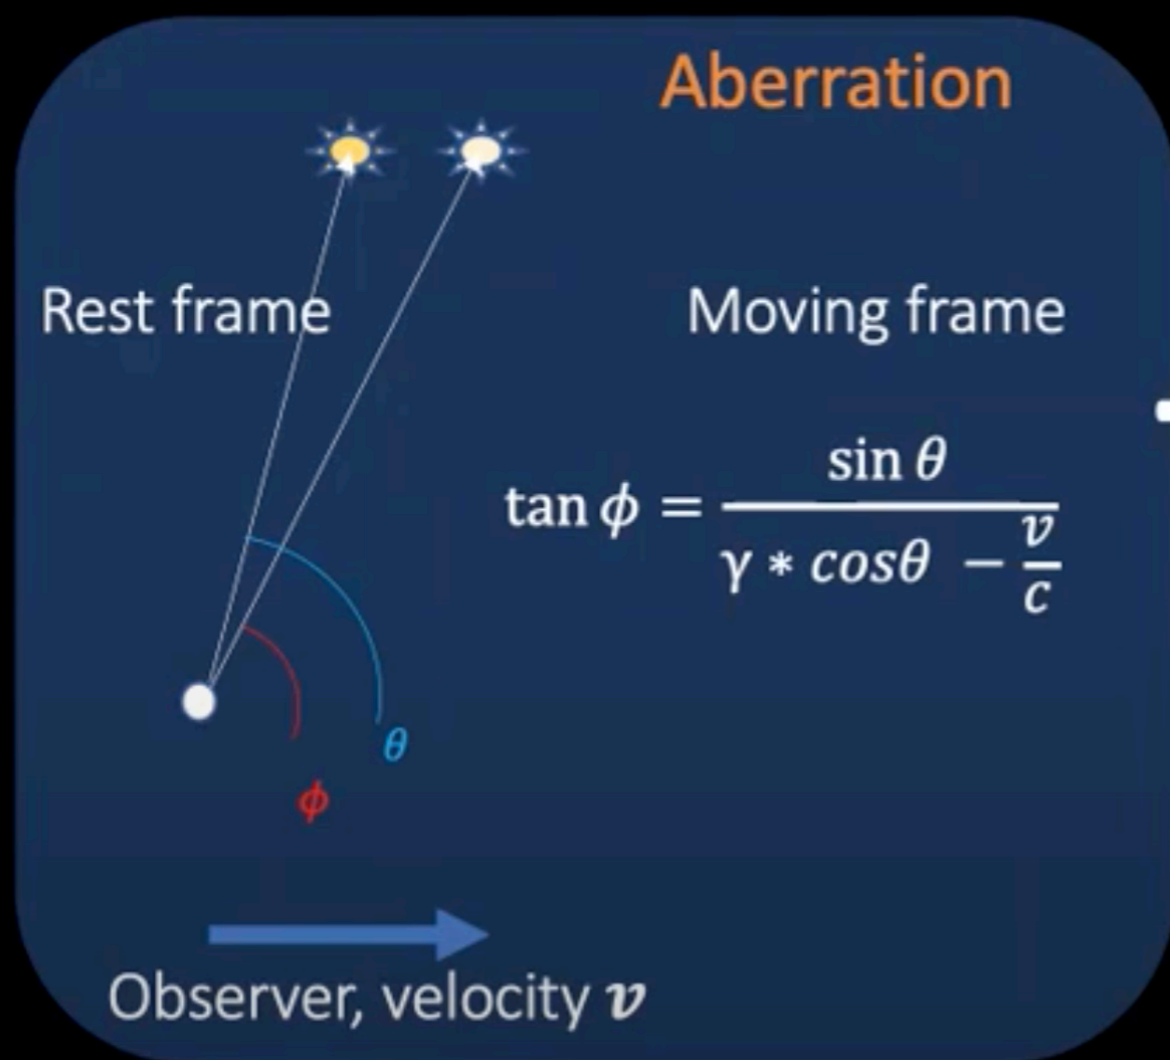

- Recently a cosmic dipole problem is reported
- If it originates from dark matter isocurvature, thermal dark matter is not favored
- The dipole may point to the first evidence of axion

The real reason, though, for our adherence here to the Cosmological Principle is not that it is surely correct, but rather, that it allows us to make use of the extremely limited data provided to cosmology by observational astronomy. If we make any weaker assumptions, as in the anisotropic or hierarchical models, then the metric would contain so many undetermined functions (whether or not we use the field equations) that the data would be hopelessly inadequate to determine the metric. On the other hand, by adopting the rather restrictive mathematical framework described in this chapter, we have a real chance of confronting theory with observation. If the data will not fit into this framework, we shall be able to conclude that either the Cosmological Principle or the Principle of Equivalence is wrong. Nothing could be more interesting.

Steven Weinberg, Gravitation and Cosmology (1972)

IF THE DIPOLE IN THE CMB IS DUE TO OUR MOTION WRT THE 'CMB FRAME'  
 THEN WE SHOULD SEE *SIMILAR* DIPOLE IN THE DISTRIBUTION OF DISTANT SOURCES

$$\sigma(\theta)_{obs} = \sigma_{rest} \left[ 1 + \left[ 2 + x(1 + \alpha) \right] \frac{v}{c} \cos(\theta) \right]$$

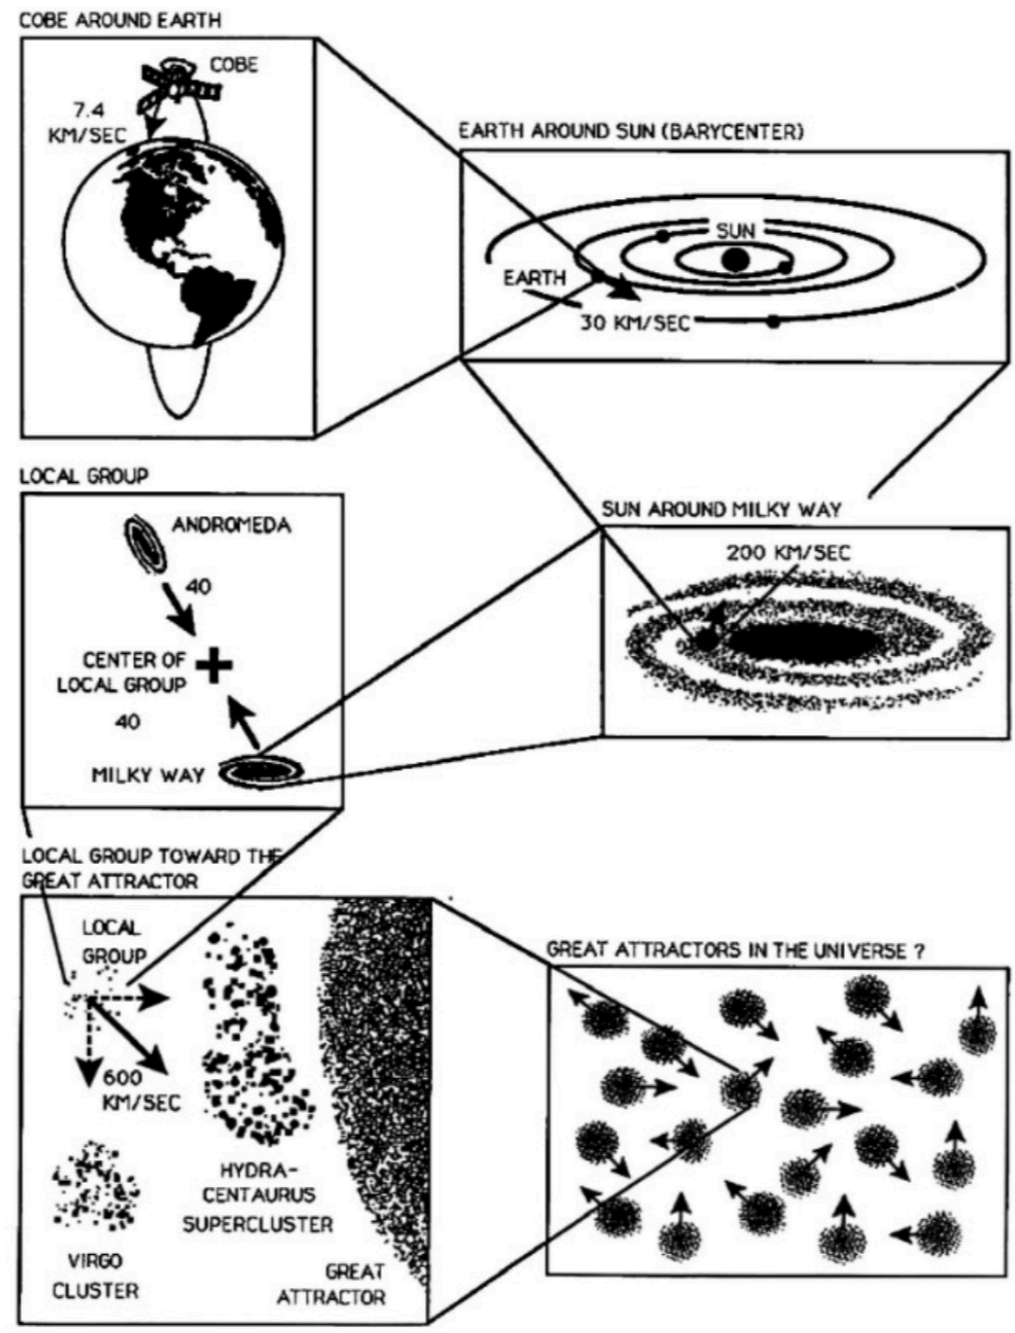

+

Flux-limited catalog  $\rightarrow$  *more* sources in direction of motion

Ellis & Baldwin,  
 MNRAS 206:377,1984

### VELOCITY COMPONENTS OF THE OBSERVED CMB DIPOLE

# Statistics in CMB

$$\frac{\Delta T}{T}(\hat{n}) = \sum_{l,m} a_{lm} Y_{lm}(\hat{n})$$

$$a_{lm} = \int d\Omega \frac{\Delta T}{T}(\hat{n}) Y_{lm}^*(\hat{n})$$

$$C_l = \frac{1}{2l+1} \sum_m \langle a_{lm}^* a_{lm} \rangle$$

$l=0,1,2,3\dots$  monopole, dipole, quadrupole...

$$\mathcal{D}_l = \frac{l(l+1)}{2\pi} C_l$$

# Aberration & Doppler boosting

Galaxies / quasars in CMB "rest frame"

Aberration: object positions compressed in direction of motion

Doppler boosting: too-faint objects boosted into catalog flux limit

From Nathan Secrest

$$g_{A\gamma\gamma} = \frac{\alpha}{2\pi f_A} \left( \frac{E}{N} - 1.92(4) \right) \quad m_A = 5.691(51) \left( \frac{10^9 \text{ GeV}}{f_A} \right) \text{ meV}$$
