Outline

- ◇ Introduction
- ◇ The evidence
- ◇ Our main contribution
- ◇ Future plan

Higgs Production

- ◆ Higgs is predicted by Standard Model of particle physics, who gives mass to all other massive particles.
- ◆ Production mechanisms:

ggF

VBF

H → WW decay

- ◆ Higgs has several main decay channels:
- ◆ $H \rightarrow WW^* \rightarrow \nu\bar{\nu}$ channel covers a wide m_H range.
- ◆ HWW Decay Product:
 - ◆ Two high energy leptons
 - ◆ Missing energy (denoted as E_T^{miss}) due to invisible neutrinos

Background Processes

- ◆ Potential backgrounds(have similar final state products as $H \rightarrow WW$):
- ◆ $t\bar{t}$ and Wt : $t/\bar{t} \rightarrow W^+ / W^- + b/\bar{b}$
- ◆ Non resonant WW production
- ◆ W +jets: one jet might be recognized as a lepton
- ◆ Z/γ^* +jets: $Z/\gamma^* \rightarrow l^+ l^-$, fake E_T^{miss} from fail reconstructed jets
- ◆ WZ , $W\gamma$ and $W\gamma^*$: one lepton of three is not well constructed.
- ◆ ZZ : $Z \rightarrow l^+ l^-$

Event Selection I

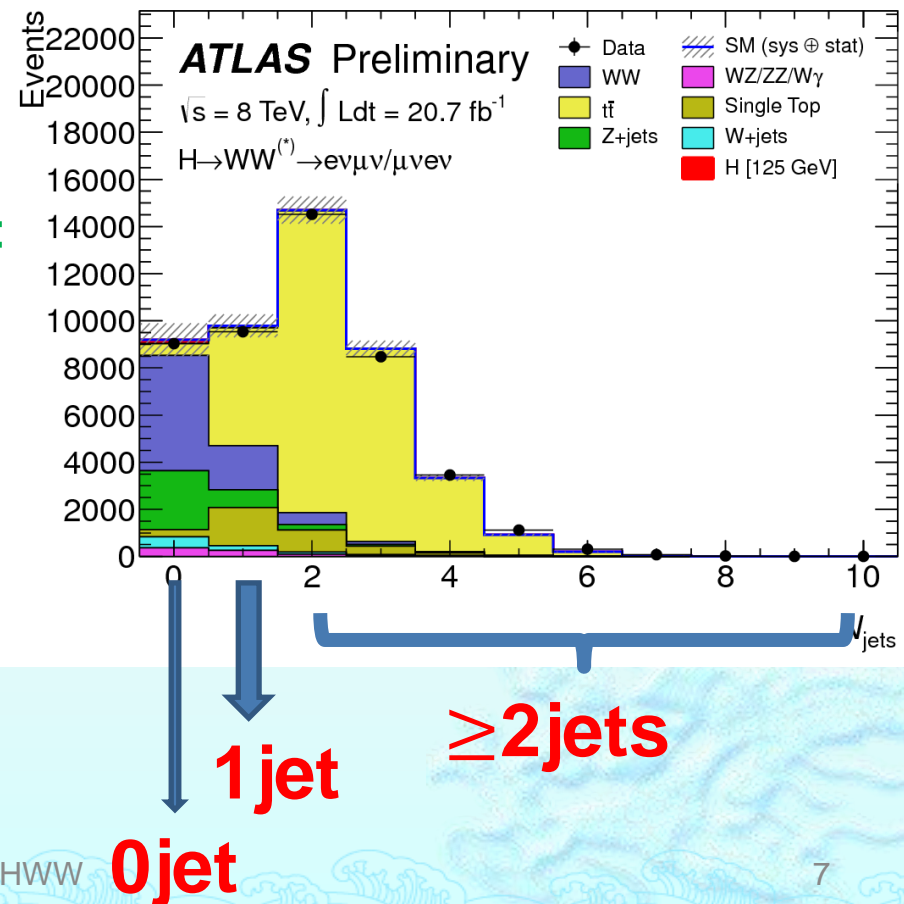

- ◆ Cuts are designed to filter those backgrounds, while keeping the signal.
- ◆ Two high energy opposite sign leptons. Suppress W+jets.
- ◆ Low m_{ll} cut, suppress low mass γ^* +jets
- ◆ Z veto: requiring m_{ll} far away from m_Z , suppress Z+jets
- ◆ Low $E_{T,rel}^{miss}$ and $P_{T,rel}^{miss}$ cut, suppress Z/ γ^* +jets

Event Selection II

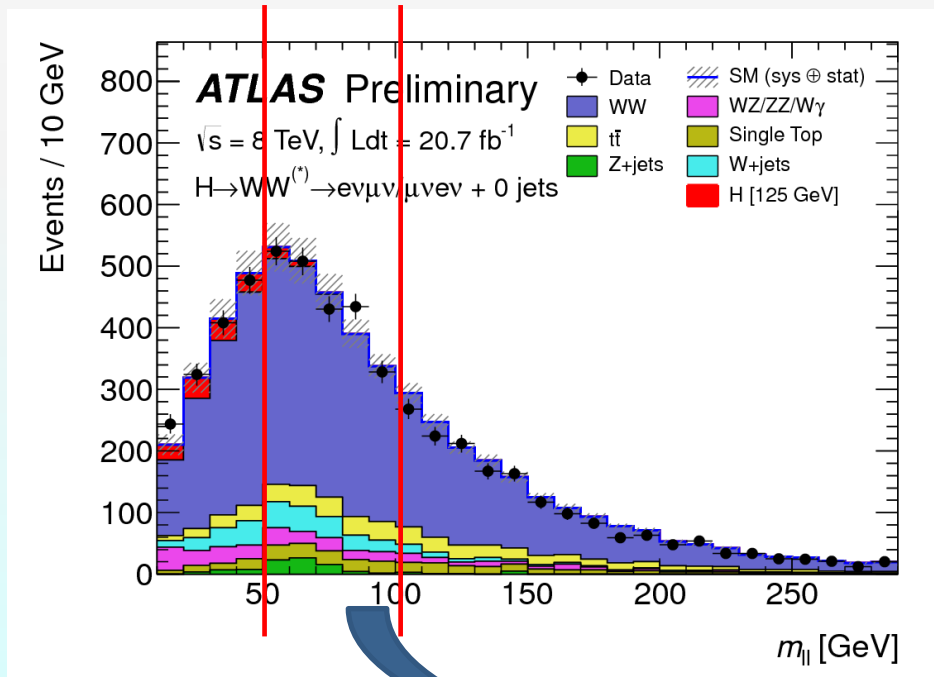

- ◆ The analysis is further divided into 3 sub-channels according to the jet multiplicity. (since the backgrounds composition are different in each jet channel)
- ◆ Cuts special to each sub-channel:
 - ◆ Bjet veto in 1jet and ≥ 2 jets
 - ◆ $Z \rightarrow \tau\tau$ veto in 1jet and ≥ 2 jets
- ◆ Cuts common to each sub-channel:
 - ◆ Upper cut for m_{ll}
 - ◆ Small $\Delta\phi_{ll}$ (spin correlation)

| Signal | ggF 125 GeV | VBF 125 GeV |
|--------|-------------|-------------|
| 0 jet | 60.8% | 8.5% |
| 1 jet | 26.8% | 37.7% |
| 2 jets | 13.1% | 54.4% |

Background determination

- ◆ General idea: use data whenever possible
- ◆ W+jets: fully data-driven
- ◆ WW, top, Z+jets use Control regions to fix the MC with the NF
- ◆ WZ/ZZ/W γ *, small contribution, MC based

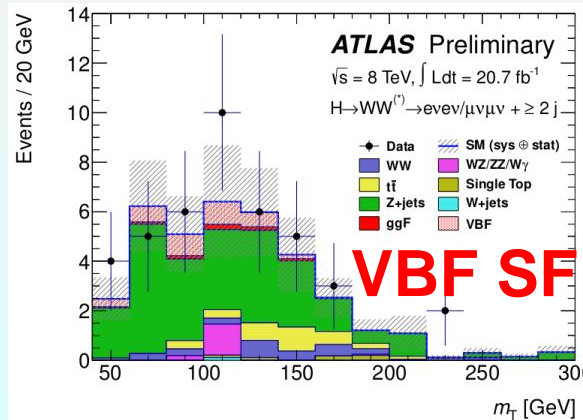

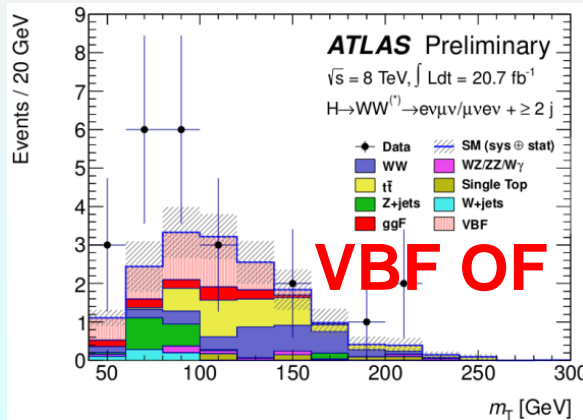

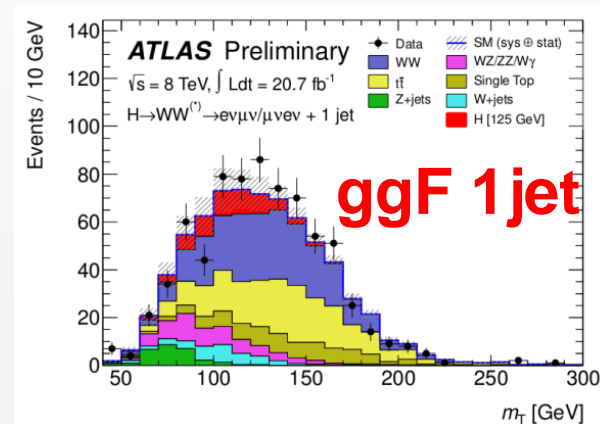

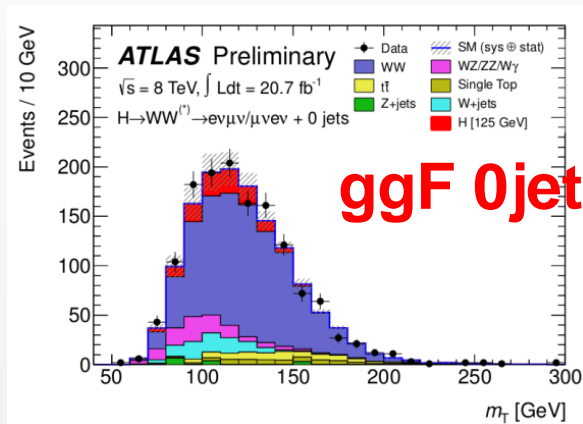

$$m_T = \sqrt{(E_T^{ll} + E_T^{\nu\nu})^2 - (\vec{p}_T^{ll} + \vec{p}_T^{\text{miss}})^2}$$

$$E_T^{ll} = \sqrt{\vec{p}_T^{ll^2} + m_{ll}^2} \text{ and } E_T^{\nu\nu} = |\vec{p}_T^{\text{miss}}|$$

The Evidence: m_T distribution

- ◆ m_T distribution of the final selected sample of all jet multiplicity channels.(input for the fit)

The Evidence: Statistical Conclusion I

—Production Rate

- After combining 2011 and 2012 data, an excess of events over the expected background is observed for $m_H \leq 150$ GeV with the largest significance of 4.1 standard deviations ($p_0 = 2 \times 10^{-5}$) at $m_H = 140$ GeV. The signal significance at $m_H = 125$ GeV is 3.8 standard deviations ($p_0 = 8 \times 10^{-5}$).
- the best fit signal strength at $m_H = 125$ GeV is $\mu = 1.01 \pm 0.31$.

The Evidence: Statistical Conclusion II

—Spin Properties

- Two hypothesis have been compared, using only 2012 data: the standard model Higgs with $J^P=0^+$, and graviton like tensor with minimal couplings with $J^P=2^+$
- The tested 2^+ hypothesis is excluded in favour of a 0^+ hypothesis at a confidence level which varies between 99% for $f_{qq} = 100\%$ and 95% for $f_{qq} = 0\%$.

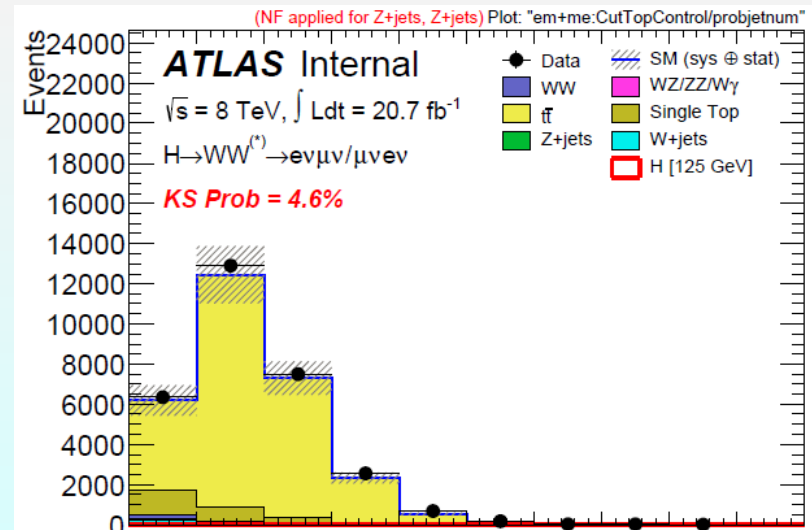

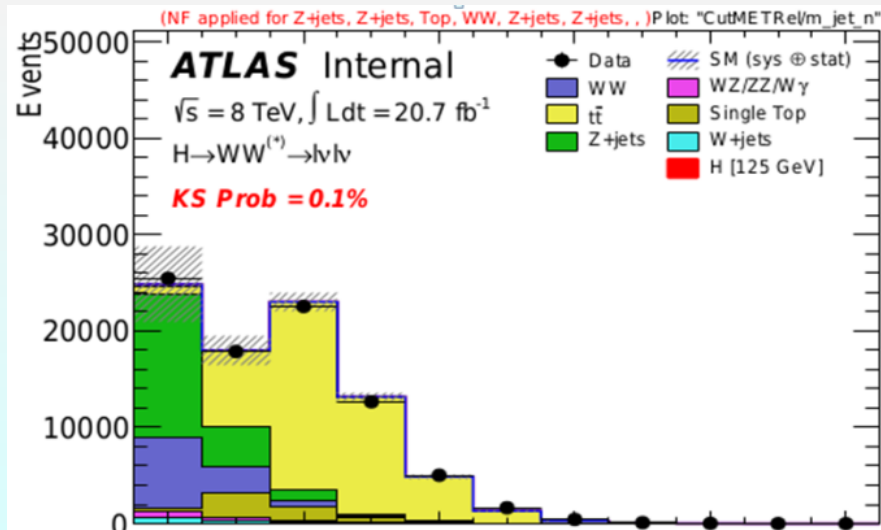

Main contribution: top 0jet estimation

- In the top background estimation in 0jet channel, the so-called JVSP method is used.

$$N_{\text{Top}_0\text{jet}}^{\text{estimated}} = N_{\text{top}_{\text{all}}}^{\text{Data}} \times f_{0j}^{\text{MC}} \times \left(\frac{f_{0 \text{ prob. jet}}^{\text{Btag,Data}}}{f_{0 \text{ prob. jet}}^{\text{Btag,MC}}} \right)^2$$

- $N_{\text{Top}_0\text{jet}}^{\text{estimated}}$ is the top event with 0 jet and $N_{\text{top}_{\text{all}}}^{\text{Data}}$ is the top events with all jets
- f_{0j}^{MC} is the JVSP—Jet Veto Survival Probability, calculated in simulation.(figure 10 left)
- $\left(\frac{f_{0 \text{ prob. jet}}^{\text{Btag,Data}}}{f_{0 \text{ prob. jet}}^{\text{Btag,MC}}} \right)^2$ is a correction applied to f_{0j}^{MC} , derived from a b-tagged top control region.
- $f_{0 \text{ prob. jet}}^{\text{Btag,Data}}$ or $f_{0 \text{ prob. jet}}^{\text{Btag,MC}}$ is the fraction of event with no probing jet in data/MC(figure 10 right)
- Probing jet is defined as jets in event with a distance from the b-jet $\Delta R > 1$.

Main contribution: top 0jet estimation

- ◆ Main experimental systematics(only those varied large than 1%):

| Experiamental Systematic s | Variation(%) |
|----------------------------|--------------|
| BJetWeight | -3.1/+4.4 |
| BJetEnergyScale | -2.0/+2.4 |
| FlavRespJetEnergyScale | +1.0/-1.1 |

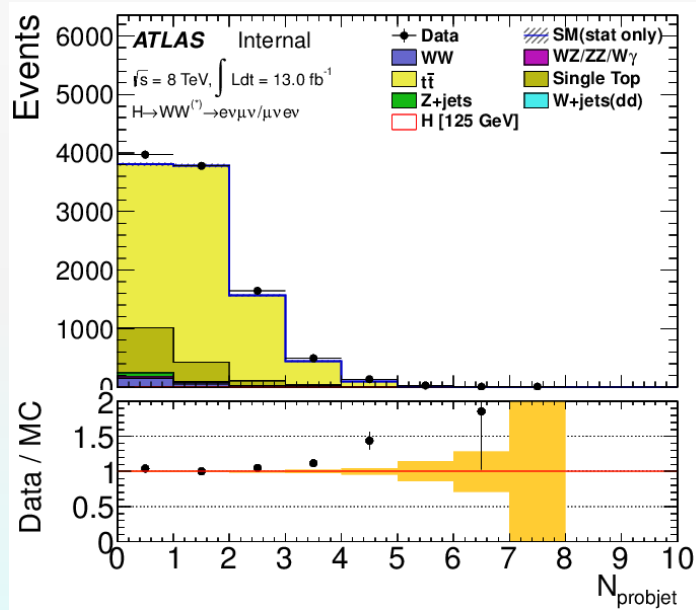

- ◆ Theoretical systematics(this is the main systematics in top 0j estimate)

| Theoretical Systematics | Variation(%) |
|--|--------------|
| Renormalization and Factorization scale(LO, old) | 7.5 |
| Sintle top- $t\bar{t}$ interference(LO,old) | 4.5 |
| Initial/final state radiation | 4.0 |
| MC generator/parton shower+hadronization | < 2.2 |

- ◆ Total systematics: 11.4%

Main contribution: b-tagged sample dependency of top 0jet estimation

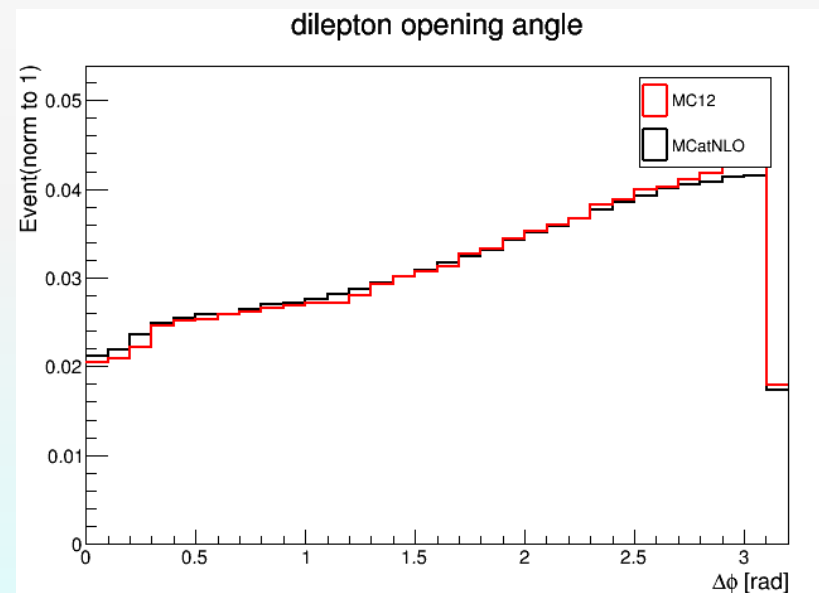

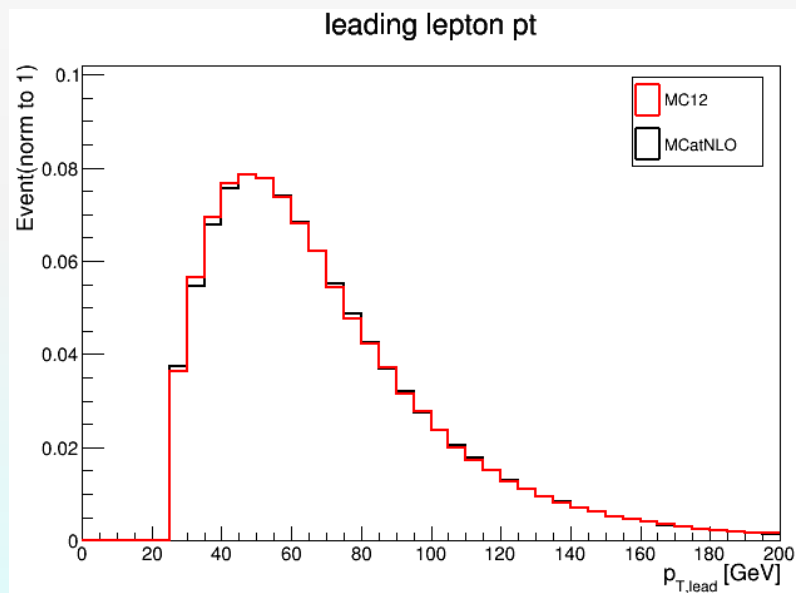

- ◆ To check the influence of b tagging on the top 0jet estimation, results are compared by using two top control samples: one sample requiring at least one b-jet, the other sample requiring exactly one b-jet.

- ◆ Results data/MC: $1.064 \pm 0.052(=1\text{b-jet})$ $1.035 \pm 0.046(\geq 1\text{b-jet})$
- ◆ Conclusion: the data/MC ratio is stable wrt. the b-jet control sample.

Main contribution: on-going improved theoretical uncertainty reevaluation

- ◆ Renormalization and Factorization scale uncertainties and single top-ttbar interference uncertainty are being reevaluated using MCatNLO.
- ◆ Here are some performance plots of the reevaluation.

Main contribution: on-going improved theoretical uncertainty reevaluation

- Systematic Table of the value of $f_{0j}^{MC} / (f_{0\text{prob jet}}^{MC})^2$ for different choice of the Renormalization(RF) and Factorization(FF) factors.

| | FF=0.5 | FF=1 | FF=2 |
|--------|------------------------------------|------------------------------------|------------------------------------|
| RF=0.5 | 0.5040 ± 0.0021 (-0.8±0.4)% | 0.5132 ± 0.0022 (+1.0±0.4)% | 0.5172 ± 0.0023 (+1.8±0.4)% |
| RF=1 | 0.5050 ± 0.0020 (-0.6±0.4)% | 0.5080 ± 0.0020 | 0.5101 ± 0.002 (+0.4±0.4)% |
| RF=2 | 0.5027 ± 0.0019 (-1.1±0.4)% | 0.5080 ± 0.0019 (<0.1±0.4)% | 0.5048 ± 0.0019 (-0.6±0.4)% |

- The maximum variation is chosen to be the systematic err: 1.8%
- Single top-t \bar{t} interference uncertainty(Diagram Subtraction(DS) vs. Removal(DR))

| | DS | DR |
|---|---------------------|------------------------------------|
| $f_{0j}^{MC} / (f_{0\text{prob jet}}^{MC})^2$ | 0.5080 ± 0.0020 | 0.5098 ± 0.0019 (+0.4±0.4)% |

Main contribution: Low pt Analysis

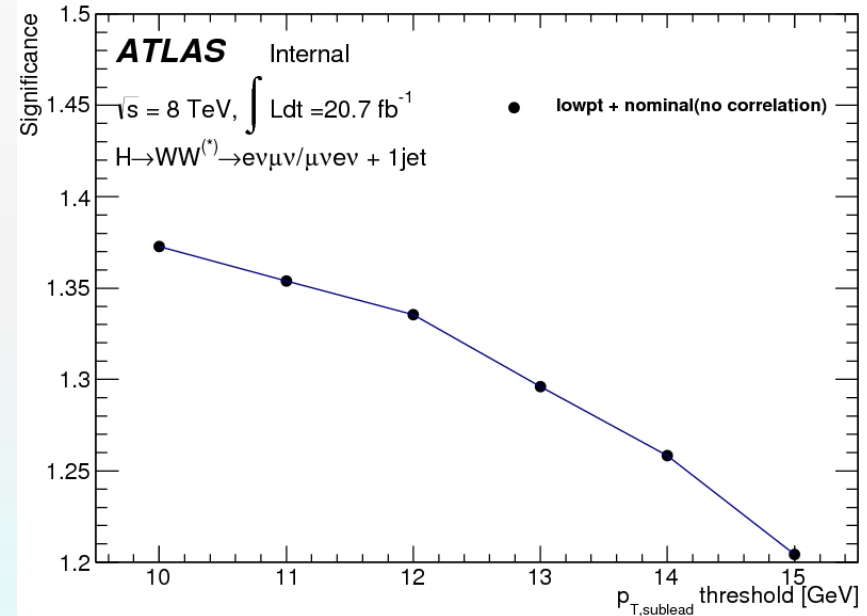

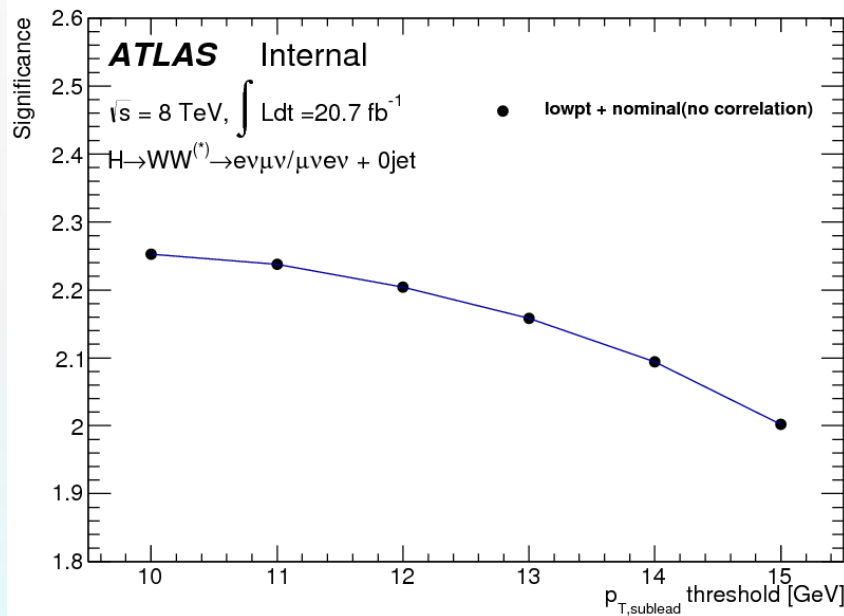

- ◆ An estimation of the significance gain is done using the same sets of cuts as nominal analysis for the OF 0/1 jet channel.
- ◆ The formula of the significance calculation.
 - ◆ lowpt+nominal significance(no correlation):

$$\text{sig} = \frac{S_{\text{lowpt}} + S_{\text{nominal}}}{\sqrt{B_{\text{lowpt}} + B_{\text{nominal}} + \delta_{B_{\text{lowpt}}}^2 + \delta_{B_{\text{nominal}}}^2}}$$

- ◆ uncertainty of background is assumed to be the same in lowpt and nominal analysis

Main contribution: Low pt Analysis

- Results: Significance gain distributions are show below for OF 0/1 jet channel. Low pt alone significance is also show for comparison

- Significance gain: 12.5%(14.0%) for 0(1) jet

Future plan: New FCPPL and New Program

- ◆ We have new team this year:

| New FCPPL team(2013) | |
|----------------------|---------------|
| LAL | NJU/USTC |
| Zhiqing Zhang | Shenjian Chen |
| Sebasien Binet | Yingchun Zhu |
| Yichen Li(joint PhD) | |

- ◆ The new program in the future:

| New Programs | |
|--|------------------------------|
| 1.Low Pt Analysis | Re-optimize selection cuts |
| | Use multivariate technique |
| | Improve background rejection |
| 2.Perform Higgs property measurement | |
| 3.Search for heavy neutral Higgs boson in the WW channel | |

That's all! Thank you!

Back up: sub-threshold b-jet veto

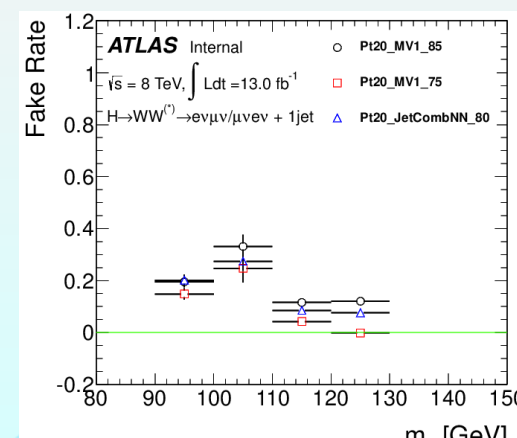

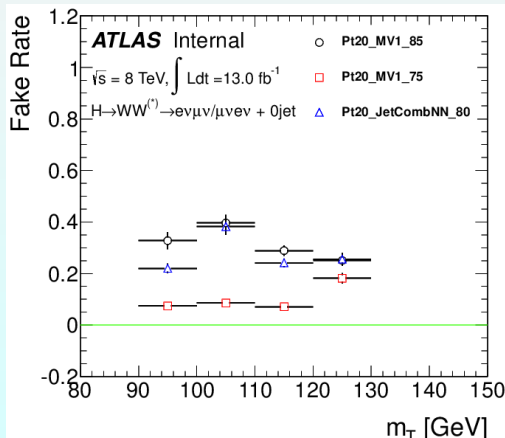

- ◆ An attempt of applying sub-threshold b-jet veto cut to further suppress top background in the signal region is made.
- ◆ Three cases are considered:
 - ◆ MV1 algorithm working at 85%
 - ◆ MV1 algorithm working at 75%
 - ◆ JetCombNN algorithm working at 80%

Back up: sub-threshold b-jet veto

- ◆ **Top reduction rates:** the fraction of top events excluded by sub-threshold b jet veto

- ◆ **Fake rate:** the fraction of non-top events in the events excluded by sub-threshold b veto

Back up: sub-threshold b-jet veto

◆ Conclusion:

- ◆ Sub-threshold b jet veto is **more efficient** in 0jet channel than in 1jet channel.
- ◆ All three b veto cases share almost the **same ability of top reduction**.
- ◆ The **MV1_75** has the smallest fake rate.
