Motivations for precise luminometry
QED scattering processes & radiative corrections
The event generator BabaYaga
  • theoretical framework
  • from BabaYaga 2.0 to BabaYaga@NLO
Phenomenological results
Independent calculations and tuned comparisons
Theoretical accuracy
Example run
Conclusions and outlook

Why precision luminosity generators?

- Precision measurements require a precise knowledge of the machine luminosity.
- e.g. the measurement of the $R(s)$ ratio is a key ingredient for the predictions of $a_\mu = (g_\mu - 2)/2$ and $\Delta \alpha_{\text{had}}(M_Z^2)$ and in turn for SM precision tests.

\[
a_\mu = \frac{\alpha^2}{3\pi^2} \int_{m_\pi^2}^{\infty} ds \frac{K(s)}{s} R(s) \quad \text{and} \quad \Delta \alpha_{\text{had}}^{(5)}(M_Z^2) = -\frac{\alpha M_Z^2}{3\pi} \text{Re} \int_{m_\pi^2}^{\infty} \frac{R(s)ds}{s(s - M_Z^2 - i\epsilon)}
\]
Reference processes for luminosity

- Instead of getting it from machine parameters, it’s more effective to exploit the relation (e.g. LEP!)

\[ L = \int \mathcal{L} dt = \frac{N}{\sigma_{th}} \quad \frac{\delta L}{L} = \frac{\delta N}{N} \oplus \frac{\delta \sigma_{th}}{\sigma_{th}} \]

- Normalization processes are required to have a clean topology, high statistics and be calculable with high theoretical accuracy

- Large-angle QED processes as \( e^+ e^- \rightarrow e^+ e^- \) (Bhabha), \( e^+ e^- \rightarrow \gamma \gamma \), \( e^+ e^- \rightarrow \mu^+ \mu^- \) are golden processes to achieve a typical precision at the level of \( 0.1\% \div \mathcal{O}(1\%) \)

- High theoretical accuracy and comparison with data require precision Monte Carlo (MC) tools, which must include (QED) radiative corrections (RC) at the highest standard as possible

- **BabaYaga** has been developed to this purpose
Example of QED RC

* Born (leading order, LO) Bhabha diagrams

\[ \begin{align*}
\text{a) } & \quad p_-, \sigma_- \quad q_-, \rho_- \\
& \quad k = p_+ + p_-
\end{align*} \]

\[ \begin{align*}
\text{b) } & \quad p_+, \sigma_+ \quad q_+, \rho_+ \\
& \quad k = q_- - p_-
\end{align*} \]

* some of QED corrected diagrams (next-to-LO, NLO), virtual & real RC

\[ \begin{align*}
\text{a) } & \quad p_- \quad q_- \\
& \quad k
\end{align*} \]

\[ \begin{align*}
\text{b) } & \quad p_+ \quad q_+ \\
& \quad k
\end{align*} \]

\[ \begin{align*}
\text{c) } & \quad p_- \quad q_- \\
& \quad k
\end{align*} \]
The Structure Function (SF) approach

- an effective way to account for [some of the] QED RC is the SF approach

\[
\sigma_{\text{corrected}} = \int dx_- dx_+ dy_- dy_+ \int d\Omega D(x_-, Q^2) D(x_+, Q^2) \\
\times D(y_-, Q^2) D(y_+, Q^2) \frac{d\sigma_0}{d\Omega} (x_- x_+ s, \theta) \Theta(\text{cuts})
\]
The Structure Function approach

- $D(x, Q^2)$ is the QED SF, to account for QED virtual and real RC up to all orders in $\alpha$ in leading-log (LL) and collinear approximation. It has a probabilistic interpretation.
- The (non-singlet) SF is the solution of the DGLAP eq. in QED

$$Q^2 \frac{\partial}{\partial Q^2} D(x, Q^2) = \frac{\alpha}{2\pi} \int_x^1 \frac{dy}{y} P_+(y) D\left(\frac{x}{y}, Q^2\right)$$

$$P_+(x) = \frac{1 + x^2}{1 - x} - \delta(1 - x) \int_0^1 dt P(t)$$

- $D(x, Q^2)$ resums (exponentiates) all the (numerically) large collinear, $L = \log \frac{s}{m_c^2}$, and infrared logarithms, which are “universal” and factorize over the kernel $x$-section.
- Solutions are analytically known (approximated, or exact with Mellin transform), but “exclusive” information are lost.
alternative, DGLAP eq. can be numerically (and exactly) solved by means of the Parton Shower (PS) MC algorithm

\[ e \rightarrow e' + \gamma \] branching kinematics recoverable (exclusive photons generation)

★ Sudakov Form Factor

\[ \Pi(s, s') = \exp \left[ -\frac{\alpha^2}{2\pi} \ln \frac{s}{s'} \int_{0}^{x^+} P(x) dx \right] \]

★ iterative solution of DGLAP equation

\[ D(x, s) = \Pi(s, m^2) \delta(1 - x) \]
\[ + \frac{\alpha}{2\pi} \int_{m^2}^{s} \Pi(s, s') \frac{ds'}{s'} \Pi(s', m^2) \times \]
\[ \int_{0}^{x^+} dy P(y) \delta(x - y) + \]
\[ + 2 \text{ branchings} \quad + 3 \quad + \cdots \]
The QED Parton Shower

★ Advantages:
- PS is an exact numerical solution of DGLAP eq. $\rightarrow$ QED RC are accounted for up to at all orders (at least in LL approx.) $\rightarrow$ multiple photon effects
- at each branching, kinematical variables are generated (energies, virtualities) to reconstruct the emitted photons’ momenta $\rightarrow$ fully exclusive event generation
- it can be truncated at $O(\alpha)$, to consistently compare with exact $O(\alpha)$ calculations

★ Disadvantages:
- initial-final (I-F) state radiation interference effects not naturally included (but they can be included!)
- the theoretical error on the x-section starts already at $O(\alpha)$, at the level of non-log contributions $\rightarrow$ this requires the matching with exact $O(\alpha)$ (NLO) RC
- a matching algorithm has been implemented in BabaYaga@NLO
Improving photon angular distribution in QED PS

- **BabaYaga 2.0** was based on a pure LL PS, without I-F state radiation interference effects
- these were added in **BabaYaga 3.5**

- **LL recipe** \((p_{1,2,3,4} \rightarrow \text{lepton momenta, } k \rightarrow \text{photon momentum})\)

\[
\cos \theta_{\gamma} \sim \frac{1}{p_1 \cdot k} + \frac{1}{p_2 \cdot k} + \frac{1}{p_3 \cdot k} + \frac{1}{p_4 \cdot k}
\]

- **Coherent Radiation** recipe for the emission of \(n\) soft photons

\[
d\sigma_n \approx d\sigma_0 \frac{1}{n!} \prod_{l=1}^{n} \frac{e^2 d^3 k_l}{(2\pi)^3 2k_l^0} \sum_{i,j} \eta_i \eta_j \frac{p_i \cdot p_j}{(p_i \cdot k_l)(p_j \cdot k_l)}
\]

E. g., \(n = 1\):

\[
\frac{p_1 \cdot p_2}{(p_1 \cdot k)(p_2 \cdot k)} + \frac{p_3 \cdot p_4}{(p_3 \cdot k)(p_4 \cdot k)} + \frac{p_1 \cdot p_3}{(p_1 \cdot k)(p_3 \cdot k)} - \frac{p_1 \cdot p_4}{(p_1 \cdot k)(p_4 \cdot k)} - \frac{p_2 \cdot p_3}{(p_2 \cdot k)(p_3 \cdot k)} + \frac{p_2 \cdot p_4}{(p_2 \cdot k)(p_4 \cdot k)}
\]

**LL + I.-F. INTERFERENCES !!**
Assessing PS theoretical accuracy

- the PS can be truncated at $O(\alpha)$ (1-photon LL RC), allowing a consistent comparison with exact NLO calculations (which are implemented e.g. in LABSPV) to assess its theoretical accuracy
- the exact NLO x-section can be written

$$\sigma_{\text{exact}}^{(\alpha)} = \sigma_{S+V}^{(\alpha)}(E_\gamma < k_0) + \sigma_H^{(\alpha)}(E_\gamma > k_0, \text{cuts})$$

where

1. \[ \sigma_{S+V}^{(\alpha),i} = \sigma_0 \left\{ 1 + 2 (\beta_e + \beta_{\text{int}}) \ln \frac{k_0}{E} + C_F^i \right\}, \quad i = s, t, s-t \]
    - M. Caffo, E. Remiddi et al., CERN Report 89-08

2. \[ \sigma_H^{(\alpha)} \text{ “exact” hard bremsstrahlung matrix elements} \]

- $k_0$ is a fictitious (and arbitrary) soft-hard photon separator and

$$\beta_e \propto \frac{\alpha}{\pi} \log \frac{s}{m_e^2}$$
PS vs. exact NLO

- experimental setup as for KLOE luminometry is considered, $\sqrt{s} = 1.019$ GeV, $E_{\text{min}}^\pm = 0.4$ GeV, $20^\circ \leq \vartheta^\pm \leq 160^\circ$, $\xi \leq 10^\circ$
PS accuracy

- distributions can be improved a lot by including I-F interferences
- the th. error is still at the level of NLO non-log corrections
- e.g. in typical setup for KLOE (as a function of the acollinearity cut, for $20^\circ - 160^\circ$ and $50^\circ - 130^\circ$ acceptances) the missing $\mathcal{O}(\alpha)$ terms amount to $\sim 0.5\%$

BabaYaga 2.0 and 3.5 accuracy (for Bhabha) = 0.5%
Multiple-photon effects (higher-order corrections)

- Nevertheless, the PS allows to take into account multiple-photon emissions, which are not negligible at the 1% level.
Matching PS with NLO

- In order to achieve the desired theoretical accuracy (a few 0.1%), both non-log $O(\alpha)$ and h.o. RC must be included.
- This requires the matching of the PS with NLO RC (widely discussed also in QCD).
- A number of highly non-trivial technical issues arises and must be solved (negative weights, double counting, exact $n$-body phase space integration, ...).
- The matching algorithm must preserve the advantages of both PS and exact calculations:
  - complete exact $O(\alpha)$ corrections
  - multiple-photon emission (h.o. corrections), at least in LL approx
  - exclusive event generation
- such an algorithm has been devised and implemented in BabaYaga@NLO.
PS and exact $\mathcal{O}(\alpha)$ (NLO) matrix elements must be combined and matched. How?

- $d\sigma_{LL}^\infty = \Pi(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} |M_{n,LL}|^2 d\Phi_n$
- $d\sigma_{LL}^\alpha = [1 + C_{\alpha,LL}] |M_0|^2 d\Phi_0 + |M_{1,LL}|^2 d\Phi_1 \equiv d\sigma_{SV}(\varepsilon) + d\sigma_H(\varepsilon)$
- $d\sigma_{\text{exact}}^\alpha = [1 + C_{\alpha}] |M_0|^2 d\Phi_0 + |M_1|^2 d\Phi_1$
- $F_{SV} = 1 + (C_{\alpha} - C_{\alpha,LL}) \quad F_H = 1 + \frac{|M_1|^2 - |M_{1,LL}|^2}{|M_{1,LL}|^2}$
- $d\sigma_{\text{exact}}^\alpha \text{ at } \mathcal{O}(\alpha) = F_{SV}(1 + C_{\alpha,LL}) |M_0|^2 d\Phi_0 + F_H |M_{1,LL}|^2 d\Phi_1$
- $d\sigma_{\text{matched}}^\infty = F_{SV} \Pi(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} \left( \prod_{i=0}^{n} F_{H,i} \right) |M_{n,LL}|^2 d\Phi_n$
PS and exact $\mathcal{O}(\alpha)$ (NLO) matrix elements must be combined and matched. How?

- $d\sigma_{LL}^\infty = \Pi(Q^2, \varepsilon) \sum_{n=0}^\infty \frac{1}{n!} |M_{n,LL}|^2 d\Phi_n$

- $d\sigma_{LL}^\alpha = [1 + C_{\alpha,LL}] |M_0|^2 d\Phi_0 + |M_{1,LL}|^2 d\Phi_1 \equiv d\sigma_{SV}(\varepsilon) + d\sigma_{H}(\varepsilon)$

- $d\sigma_{\text{exact}}^\alpha = [1 + C_\alpha] |M_0|^2 d\Phi_0 + |M_1|^2 d\Phi_1$

- $F_{SV} = 1 + (C_\alpha - C_{\alpha,LL}) \quad F_H = 1 + \frac{|M_1|^2 - |M_{1,LL}|^2}{|M_{1,LL}|^2}$

- $d\sigma_{\text{exact}}^\alpha \text{ at } \mathcal{O}(\alpha) = F_{SV} (1 + C_{\alpha,LL}) |M_0|^2 d\Phi_0 + F_H |M_{1,LL}|^2 d\Phi_1$

- $d\sigma_{\text{matched}}^\infty = F_{SV} \Pi(Q^2, \varepsilon) \sum_{n=0}^\infty \frac{1}{n!} \left( \prod_{i=0}^n F_{H,i} \right) |M_{n,LL}|^2 d\Phi_n$
PS and exact $\mathcal{O}(\alpha)$ (NLO) matrix elements must be combined and matched. How?

- $d\sigma_{LL}^\infty = \prod(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} |M_{n,LL}|^2 d\Phi_n$

- $d\sigma_{LL}^\alpha = [1 + C_{\alpha,LL}] |M_0|^2 d\Phi_0 + |M_{1,LL}|^2 d\Phi_1 \equiv d\sigma_{SV}(\varepsilon) + d\sigma_{H}(\varepsilon)$

- $d\sigma_{\text{exact}}^\alpha = [1 + C_{\alpha}] |M_0|^2 d\Phi_0 + |M_1|^2 d\Phi_1$

- $F_{SV} = 1 + (C_{\alpha} - C_{\alpha,LL}) \quad F_{H} = 1 + \frac{|M_1|^2 - |M_{1,LL}|^2}{|M_{1,LL}|^2}$

- $d\sigma_{\text{exact}}^\alpha \at\mathcal{O}(\alpha) = F_{SV} (1 + C_{\alpha,LL}) |M_0|^2 d\Phi_0 + F_{H} |M_{1,LL}|^2 d\Phi_1$

- $d\sigma_{\text{matched}}^\infty = F_{SV} \prod(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} \left( \prod_{i=0}^{n} F_{H,i} \right) |M_{n,LL}|^2 d\Phi_n$
PS and exact $\mathcal{O}(\alpha)$ (NLO) matrix elements must be combined and matched. How?

- $d\sigma_{\infty}^{\alpha,LL} = \Pi(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} |M_{n,LL}|^2 d\Phi_n$
- $d\sigma_{\alpha,LL} = [1 + C_{\alpha,LL}] |M_0|^2 d\Phi_0 + |M_{1,LL}|^2 d\Phi_1 \equiv d\sigma_{SV}(\varepsilon) + d\sigma_H(\varepsilon)$
- $d\sigma_{\alpha,exact} = [1 + C_\alpha] |M_0|^2 d\Phi_0 + |M_1|^2 d\Phi_1$
- $F_{SV} = 1 + (C_\alpha - C_{\alpha,LL}) \quad F_H = 1 + \frac{|M_1|^2 - |M_{1,LL}|^2}{|M_{1,LL}|^2}$
- $d\sigma_{\alpha,exact}^{\mathcal{O}(\alpha)} = F_{SV} (1 + C_{\alpha,LL}) |M_0|^2 d\Phi_0 + F_H |M_{1,LL}|^2 d\Phi_1$

$d\sigma_{\infty,matched} = F_{SV} \Pi(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} (\prod_{i=0}^{n} F_{H,i}) |M_{n,LL}|^2 d\Phi_n$
PS and exact $\mathcal{O}(\alpha)$ (NLO) matrix elements must be combined and matched. How?

- \[ d\sigma^\infty_{LL} = \Pi(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} |M_{n,LL}|^2 \, d\Phi_n \]

- \[ d\sigma^\alpha_{LL} = [1 + C_{\alpha,LL}] |M_0|^2 d\Phi_0 + |M_{1,LL}|^2 d\Phi_1 \equiv d\sigma_{SV}(\varepsilon) + d\sigma_H(\varepsilon) \]

- \[ d\sigma_{\text{exact}}^\alpha = [1 + C_\alpha] |M_0|^2 d\Phi_0 + |M_1|^2 d\Phi_1 \]

- \[ F_{SV} = 1 + (C_\alpha - C_{\alpha,LL}) \quad F_H = 1 + \frac{|M_1|^2 - |M_{1,LL}|^2}{|M_{1,LL}|^2} \]

- \[ d\sigma_{\text{exact}}^\alpha \at \mathcal{O}(\alpha) = F_{SV} (1 + C_{\alpha,LL}) |M_0|^2 d\Phi_0 + F_H |M_{1,LL}|^2 d\Phi_1 \]

- \[ d\sigma^\infty_{\text{matched}} = F_{SV} \Pi(Q^2, \varepsilon) \sum_{n=0}^{\infty} \frac{1}{n!} \left( \prod_{i=0}^{n} F_{H,i} \right) |M_{n,LL}|^2 \, d\Phi_n \]
Contents of the *matched* formula

- $F_{SV}$ and $F_{H,i}$ are infrared safe and account for missing $O(\alpha)$ non-logs, avoiding double counting of LL
- $[\sigma^\infty_{\text{matched}}] O(\alpha) = \sigma^{\alpha}_{\text{exact}}$
- resummation of higher orders LL contributions is preserved
- the cross section is still **fully differential** in the momenta of the final state particles ($e^+, e^-$ and $n\gamma$)
- as a by-product, part of photonic $\alpha^2 L$ included by means of terms of the type $F_{SV} |_{H,i} \times LL$

G. Montagna et al., *PLB* 385 (1996)

- the th. error is shifted to $O(\alpha^2)$ (NNLO, 2 loop) not infrared terms: very naively and roughly (for photonic corrections)

\[ \frac{1}{2} \alpha^2 L \equiv \frac{1}{2} \alpha^2 \log \frac{s}{m^2} \sim 5 \times 10^{-4} \]
Vacuum Polarization (and $Z$ exchange)

- $\alpha \rightarrow \alpha(q^2) \equiv \frac{\alpha}{1-\Delta\alpha(q^2)}$

- $\Delta\alpha = \Delta\alpha_{e,\mu,\tau,\text{top}} + \Delta\alpha^{(5)}_{\text{had}}$

- $\Delta\alpha^{(5)}_{\text{had}}$ is a non-perturbative contribution. Evaluated with recently updated HADR5N by F. Jegerlehner or HMNT by Hagiwara, Teubner et al. They return also an error associated with exp. data.

- VP included both in lowest order and (at best) in one-loop diagrams $\Rightarrow$ part of the 2 loop factorizable corrections are included

- $Z$ exchange included at lowest order in $e^+e^-$ and $\mu^+\mu^-$ FS. Its effect is $O(0.1\%)$ @ 10 GeV for Bhabha
The matching procedure is now implemented in BabaYaga@NLO.

It is applied to Bhabha, $\gamma\gamma$ and $\mu^+\mu^-$ final states.

The (Fortran 77) code can be downloaded from http://www.pv.infn.it/hepcomplex/babayaga.html.

Relevant papers for all the details and phenomenological studies:

Results with \textbf{BabaYaga@NLO}

- as examples to show the features of the EG, the following setups and definitions are used (for Bhabha)

\begin{itemize}
  \item[a] $\sqrt{s} = 1.02 \text{ GeV, } E_{\text{min}} = 0.408 \text{ GeV, } 20^\circ < \theta_\pm < 160^\circ, \xi_{\text{max}} = 10^\circ$
  \item[b] $\sqrt{s} = 1.02 \text{ GeV, } E_{\text{min}} = 0.408 \text{ GeV, } 55^\circ < \theta_\pm < 125^\circ, \xi_{\text{max}} = 10^\circ$
  \item[c] $\sqrt{s} = 10 \text{ GeV, } E_{\text{min}} = 4 \text{ GeV, } 20^\circ < \theta_\pm < 160^\circ, \xi_{\text{max}} = 10^\circ$
  \item[d] $\sqrt{s} = 10 \text{ GeV, } E_{\text{min}} = 4 \text{ GeV, } 55^\circ < \theta_\pm < 125^\circ, \xi_{\text{max}} = 10^\circ$
\end{itemize}

\[
\begin{align*}
\delta_{VP} &\equiv \frac{\sigma_{0,VP} - \sigma_0}{\sigma_0} \\
\delta_{HO} &\equiv \frac{\sigma_{PS\text{ matched}} - \sigma_{NLO}^\infty}{\sigma_0} \\
\delta_{\text{non-log}} &\equiv \frac{\sigma_{NLO}^{\infty} - \sigma_{PS}^{\infty}}{\sigma_0} \\
\delta_{\alpha} &\equiv \frac{\sigma_{NLO}^{\alpha} - \sigma_0}{\sigma_0} \\
\delta_{PS} &\equiv \frac{\sigma_{PS} - \sigma_{PS}^{\infty}}{\sigma_0} \\
\delta_{\text{non-log}} &\equiv \frac{\sigma_{PS\text{ matched}} - \sigma_{PS}^{\infty}}{\sigma_0}
\end{align*}
\]

\textbf{Table:} Relative corrections (in per cent) to the Bhabha cross section for the four setups

- in short, the fact that $\delta^{non-log}_{\alpha} \simeq \delta^{non-log}_{\infty}$ and $\delta_{HO} \simeq \delta_{PS}$ means that the matching algorithm preserves both the advantages of exact NLO calculation and PS approach:
  - it includes the missing NLO RC to the PS
  - it adds the missing higher-order RC to the NLO
• acollinearity distribution, setup (a)
• $e^+e^-$ invariant-mass distribution, setup (a)
Results with **BabaYaga@NLO** for $\gamma\gamma$ final state

- $\gamma\gamma$ final state has a lower x-section, but it does not depend on hadronic VP, which is a source of th. error
- Similar setups and definitions were used to study $\gamma\gamma$ FS

\[

**Table:** Photon pair production cross sections (in nb) to different accuracy levels and relative corrections (in per cent)
Results with **BabaYaga@NLO** for $\gamma\gamma$

- most-energetic photon angle and energy, acollinearity distribution
Estimating the theoretical accuracy

- It is of utmost importance to compare with independent calculations/implementations, in order to
  - assess the technical precision, spot bugs (with the same th. ingredients)
  - estimate the theoretical “error” when including partial/incomplete higher-order corrections

- Generators exist on the marked and are used by exp. coll., some of them including QED h.o. and NLO corrections according to different approaches (collinear SF + NLO, YFS exponentiation, . . .)

Tuned comparisons

- **BabaYaga@NLO vs. Bhwide (at BABAR)**

![Graph showing tuned comparisons between BabaYaga@NLO and Bhwide](image-url)

The graph displays the relative difference in percent against the angular range (from x to 180-x degrees) for different values of x.
Tuned comparisons

- **MCGPJ vs. BabaYaga@NLO and Bhwide** (at CMD2)

![Graph](image)

Fig. 23 Relative differences between BHWIDE and MCGPJ Bhabha cross sections as a function of the acollinearity cut, for the CMD-2 experiment at VEPP-2M

- The three generators agree within 0.1% for the typical experimental acollinearity cut $\Delta \theta \sim 0.2 \div 0.3$ rad

- Main conclusion from tuned comparisons: technical precision of the generators well under control, the small remaining differences being due to slightly different details in the calculation of the same theoretical ingredients [additive vs factorized formulations, different scales for higher–order leading log corrections]
Theoretical accuracy, comparisons with NNLO calculations

- After including the exact NLO RC, the theoretical error starts at $\mathcal{O}(\alpha^2)$ (NNLO) (although large NNLO corrections are already included by means of multiple photon emission)
- The NNLO QED corrections to Bhabha scattering have been calculated in the last years → it’s very important to measure the impact of the missing (non-leading) terms of order $\alpha^2$ within typical setups for luminometry, to assess the MC accuracy
- The estimate of the theoretical accuracy will be sound and robust
- E.g., BabaYaga formulae can be truncated at $\mathcal{O}(\alpha^2)$ to be consistently compared with all the classes of NNLO corrections
the $\mathcal{O}(\alpha^2)$ content of BabaYaga cross section can be cast in the form

$$\sigma_{\alpha^2} = \sigma_{SV}^{\alpha^2} + \sigma_{SV,H}^{\alpha^2} + \sigma_{HH}^{\alpha^2}$$

where

- $\sigma_{SV}^{\alpha^2}$: soft+virtual photonic corrections up to $\mathcal{O}(\alpha^2) \rightarrow$ compared with the corresponding available NNLO QED calculation
- $\sigma_{SV,H}^{\alpha^2}$: one-loop soft+virtual corrections to single hard bremsstrahlung $\rightarrow$ presently estimated relying upon existing (partial) results
- $\sigma_{HH}^{\alpha^2}$: double hard bremsstrahlung $\rightarrow$ compared with the exact $e^+e^- \rightarrow e^+e^-\gamma\gamma$ cross section, to register really negligible differences (at the $1 \times 10^{-5}$ level)
NNLO calculations

Differences from Penin & Bonciani et al.

- Differences between Penin and Bonciani et al. and the corresponding BabaYaga content, as $f(\varepsilon)$ and $g(\log(m_e))$. E.g. LABS at 1 GeV

- Differences are infrared safe
- $\delta\sigma(\text{phot.})/\sigma_0 \propto \alpha^2 L$  
  $\delta\sigma(N_F = 1)/\sigma_0 \propto \alpha^2 L^2$
- Numerically, in LABS and VLABS,

  $$\delta\sigma(\text{phot.}) + \delta\sigma(N_F = 1) < 0.015\% \times \sigma_0$$
A Desy–Zeuthen & Katowice collaboration [H. Czyz, J. Gluza, M. Gunia, T. Riemann and M. Worek] did a **new, exact calculation of pair corrections**, based on exact NNLO soft+virtual corrections and $2 \to 4$ matrix elements $e^+e^- \to e^+e^- (l^+l^-, l = e, \mu, \tau), e^+e^- (\pi^+\pi^-)$

**Results**: in comparison with the approximation of BabaYaga@$\text{NLO}$ and using realistic KLOE and BaBar luminosity cuts (cross sections in nb)

* The uncertainty due to lepton and hadron pair corrections is at the level of a few units in $10^{-4}$ [further comparisons in progress]*
\[ \Delta \alpha^{(5)}_{\text{had}} \] and other \[ \mathcal{O}(\alpha^2) \] uncertainties

- the exact 1-loop virtual corrections to the 1-photon real emission for Bhabha only recently has been made available (comparisons in progress)
  
  Actis \textit{et al.}, Phys. Lett. B 682 (419) 2010

  - relying on the LEP experience and being the error at the \( \alpha^2 L \) level, the missing corrections are \( \leq 0.05\% \)

- the double real bremsstrahlung contribution is in principle approximated in \textbf{BabaYaga@NLO}
  
  - observed \textit{really negligible differences} with the exact matrix elements, calculated with the \textbf{ALPHA} (Caravaglions and Moretti ('95)) algorithm/routine

- \( \Delta \alpha^{(5)}_{\text{had}} \) is affected by the experimental error, which is returned by the routines in use (\textbf{HADR5N} and \textbf{HMNT})
  
  - The total error budget for Bhabha can be summarized as follow (from G. Montagna’s talk at the “International Workshop on \( e^+e^- \) collisions from \( \Phi \) to \( \Psi \)”, Beijing, October 2009)
Status of the MC theoretical accuracy

Main conclusion of the Luminosity Section of the WG Report “Radiative Corrections & MC Tools”

Putting the various sources of uncertainties (for large–angle Bhabha) all together...

- Comparisons with the Novosibirsk $\Delta\alpha_{had}^{(5)}(q^2)$ parameterization routine and with the calculation by Actis et al. for $e^+e^-\gamma$ at one loop would put the evaluation of the $|\delta_{VP}^{err}|$ and $|\delta_{SV,H,\alpha^2}^{err}|$ uncertainties on firmer grounds

- The present error estimate appears to be rather robust and sufficient for high–precision luminosity measurements. It is comparable with that achieved about ten years ago for small–angle Bhabha luminosity monitoring at LEP/SLC

\(^1\) Very preliminary, work in progress using realistic BES-III and CLEO-c luminosity cuts
\(^2\) Preliminary and assuming BaBar cuts. Work in progress for BELLE event selection
Resummation beyond $\alpha^2$

[*] with a complete 2-loop generator at hand, (leading-log) resummation beyond $\alpha^2$ can be neglected?

Figure: Impact of $\alpha^2$ (solid line) and resummation of higher order ($\geq \alpha^3$) (dotted) corrections on the acollinearity distribution

[*] resummation beyond $\alpha^2$ still important!
The “dark” side of BabaYaga

- Recently, the process $e^+e^- \rightarrow \gamma, U \rightarrow e^+e^\gamma$ (or $\rightarrow \mu^+\mu^-\gamma$) has been implemented, including LL collinear RC, for the search of a light, weakly-interacting, photon-like vector boson at flavour factories

- the $U$ boson is a candidate for dark matter

[Diagram of Feynman diagrams with dark photon exchange]

- The details can be found in arXiv:1007.4984 [hep-ph] by L. Barzè et al., submitted to PRD

- for the moment being, forget about it!
Using **BabaYaga@NLO**

- Download the package `babayaga-NLO.tar.gz`
- Unpack it `tar -xzvf babayaga-NLO.tar.gz`
- `cd babayaga-NLO/`
- Read the file `README`!
- `./configure`
- `make`
- `./babayaga`
- On the shell prompt, it should appear an “interactive” menu like this...
Welcome to BabaYaga

It is an event generator for QED processes at low energies, matching a QED PS with exact order alpha corrections

[[ it simulates: e+e- --> g --> e+e- or mu+mu- or gg ]]
[[ : e+e- --> g,U --> e+e-g or mu+mu-g ]]

Principal Menu:
[ type "run" to start generation, "legenda" for help or "quit" to quit ]
[ fs ] final state = ee
[ ecms ] CoM energy = 1.020 GeV
[ thmin ] min. angle = 20.000 deg
[ thmax ] max. angle = 160.000 deg
[ zmax ] acollinearity = 10.000 deg
[ emin ] min. energy = 0.408 GeV
[ nev ] 10000000. events will be generated
[ path ] files saved in test-run/
[ ntuple ] ntuple creation no
[ menu2 ] the second menu is off
[ menud ] the dark matter menu is off

Insert "variable value":
Using BabaYaga@NLO

- In the main menu a number of parameter can be modified, most notably:
  - final state: $ee$, $mm$ or $gg$
  - center of mass energy
  - acceptance cuts (modify $cuts.f$ for more elaborate event selection criteria)
  - directory where to save the outputs
  - enabling a 2nd menu, to modify inner parameters (order of RC, running of $\alpha$, ...)
  - type legenda for a quick explanation of the parameters and possible options, type run to start BabaYaga run

- The results are saved in a separate directory ($test-run/$ by default), which contains:
  - the unweighted events if their storage was requested
  - a number of simple text files with some relevant distributions (files to be fed to gnuplot for example)
  - the file $statistics.txt$ where the information (statistics, input parameters, results) of the run is saved
The statistics.txt file

Generating 10000000 weighted events

When there were 4 photons
Conclusions & Outlook

• Remarkable progress to reduce the theoretical error in luminosity measurement at flavour factories down to $\sim 0.1\%$

☆ Both exact NLO and multiple photon corrections are needed to reach such an accuracy and they are implemented in the most precise MC tools

☆ At least 3 EG for Bhabha scattering (BabaYaga@NLO, Bhwide, MCGPJ) agree within 0.2\% for integrated x-section and $\sim 1\%$ (or better) for distributions

• Precision generators are also available for $\gamma\gamma$ and $\mu^+\mu^-$ final states

• NNLO QED calculations allow to assess the MC theoretical accuracy at the $0.1\%$ level

• Possible and in progress improvements concern
  → Tuned comparisons: extend the study done in Bhabha to $\gamma\gamma$ and $\mu^+\mu^-[\gamma]$ processes
  → Theoretical accuracy: deeper analysis of pair corrections, 1-loop RC to $e^+e^- \rightarrow e^+e^-\gamma$ and hadronic VP
