Budker Institute of Nuclear Physics, SB RAS, 11 Lavrentieva ave., Novosibirsk, 630090, Russia

Abstract Experimental data from the PEP-II B-factory at 10.6 GeV center-of-mass (c.m.) energy, obtained via initial-state radiation (ISR) with the BaBar detector, are presented. The cross sections for many hadronic processes have been measured from the production threshold to 4–5 GeV of the $e^+e^-$ c.m. energy. The obtained data allow to study a number of intermediate states and determine the parameters of known resonances and their branching fractions. The exclusive cross section for some number of hadronic sub-processes are presented.

Key words ISR, $e^+e^-$, hadrons, BaBar

1 Introduction

The study of the $e^+e^- \rightarrow \text{hadrons}$ reaction at low c.m. energies using ISR technique became a powerful tool, thanks to the very high luminosity DAFNE, KEK-B and PEP-II colliders. Radiation of the high-energy photon from the initial particles allows a production of the hadronic system at energies much below the nominal machine energy [1, 2].

The BaBar [3] Collaboration has an intensive program to study the $e^+e^-$ cross section at low c.m. energy using ISR, when the PEP-II operates at the $Y(4S)$ resonance. A number of multi-hadron processes were studied and published. The measured cross sections made a major contribution to $R$ calculation during the last few years. Low energy hadron spectroscopy is another application of BaBar ISR study. It is shown, that spectroscopy data not only are absolutely necessary for the $R$ calculations (the total cross sections normally are the compositions of different states with different BF to certain modes), but give a lot of information about hadron dynamics in 1–2 GeV energy range. Multi-hadron events show many, sometimes unexpected structures which are not easy to separate - full partial wave analysis (PWA) is needed.

In this paper we present evidence of hadronic states in the 1.0–2.5 GeV region, some of them are not listed in the PDG, as well as the already discovered $Y(2175)$ in the $\phi(1020)f_0(980)$ decay mode, confirmed by BES and Belle. The analysis is in progress, some new results should come out soon.

2 Overview of the cross section measurements

During the last few years the BaBar Collaboration published number of papers [4–13] on measurements of the total cross section for the reactions $e^+e^- \rightarrow 2\pi$, $3\pi$, $4\pi$, $5\pi$, $6\pi$, $2K\pi$, $2K2\pi$, $4K$, $p\bar{p}$, $\Lambda\bar{\Lambda}$, $DD$, … The overview of the measured cross sections is shown in Fig. 1. With the recent published data for the $e^+e^- \rightarrow 2\pi$ process (see talk by Wen Feng) the BaBar data play dominant role in the muon $g - 2/2$ calculation (see talk by M. Davier). The only channels are missing in this line are $e^+e^- \rightarrow \pi^+\pi^-2\pi^0$, for which only preliminary results were presented and $e^+e^- \rightarrow K^+K^-$ reaction, which is still under study.

Studies of the exclusive channels of $e^+e^-$ annihilation allow to determine such fundamental parameters as mass, width and leptonic width of various vector mesons. In addition to the low-lying resonances, such as the $\rho$, $\omega$ and $\phi$, where ISR studies can independently provide meaningful and still competitive information, they are indispensable for a much more precise than before investigation of the excited vector states. Moreover, detailed analysis of the dynamics shows that in many cases a multiparticle final state...
can be reached via different intermediate mechanisms.

For example, four pions can be produced via $\omega\pi^0$, $a_1(1260)^{\pm}\pi^\mp$, $\rho^0f_0$, ... and provide information on mesons with quantum numbers differing from those of vectors.

In the following sections we show a complexity of the internal substructures observed in some channels, which are used (where possible) to extract resonance parameters.

3 Resonance physics

3.1 The $e^+e^-\rightarrow\pi^+\pi^-$ reaction

This reaction is dominated by production of the $\rho(770)$ resonance and the pion cross section behavior was relatively well studied up to about 1.4 GeV. The high statistic measurement [4] of the cross section up to 3.0 GeV of c.m. energy is presented by BaBar for the first time. This energy range, shown in Fig. 2 demonstrates some statistically significant structures, not yet explained theoretically.

3.2 The $e^+e^-\rightarrow\pi^+\pi^-\pi^0$ reaction

The three pion reaction study in the ISR process was published by BaBar in Ref. [5] and measured $e^+e^-\rightarrow\pi^+\pi^-\pi^0$ cross section is dominated by the well known $\phi(1020)$, $\omega(780)$ and $J/\psi$ resonances. Large statistics allow the observation of two structures in the 1.0–2.0 GeV region in agreement with SND measurement [14] below 1.4 GeV and in disagreement with old DM2 results [15] at higher energies.

We fit this region (see Fig. 3) assuming the presence of two excited $\omega(1420)$ and $\omega(1650)$ [21] states and determine their parameters. Note, that the parameters of these states are still not well determined.
and in our case they strongly depend on relative phases with \( \omega(780) \) and \( \phi(1020) \) resonances having much larger decay rate to this mode.

### 3.3 The \( e^+e^- \rightarrow \pi^+\pi^- \pi^+\pi^- \), \( \pi^+\pi^- 2\pi^0 \) reactions

These reactions have the largest cross sections in the studied energy region after \( e^+e^- \rightarrow \pi^+\pi^- \). They were studied with the Babar detector [6, 7] in much wider energy range than any previous experiment. The intermediate resonance production of \( \omega\pi^0 \) in the \( \pi^+\pi^- 2\pi^0 \) final state and \( a_3\pi \) dominance in both reactions were previously reported. The cross section shape for both reactions shows a wide structure peaked at 1.5 GeV which cannot be described as a single resonance and a "shoulder" just below 2 GeV which also has no explanation.

![Fig. 5. The \( e^+e^- \rightarrow \phi\eta, \phi\pi^0 \) cross sections measured with the BaBar detector.](image)

### 3.5 The \( e^+e^- \rightarrow K^+K^-\pi^+\pi^- (\pi^0\pi^0) \) reactions

The only measurement available refer to the study on the fully charged mode, performed by DM2 with about 100 times less data. The \( e^+e^- \rightarrow K^+K^-\pi^0\pi^0 \) reaction never was studied before. It is shown by BaBar that these reactions are dominated by \( K^*(892)^0K^+\pi^0 \) and \( K^*(892)^+K^0\pi^0 \) intermediate states [11] (see Fig. 6), but \( K^*(892)K^*(892) \) decay mode is not seen.

![Fig. 6. Scatter plots \( m(K^-\pi^+) \) vs. \( m(K^+\pi^-) \) (a) and projection \( m(K^+\pi^-) \) plot (b, two entries per event) for the \( e^+e^- \rightarrow K^+K^-\pi^+\pi^- \) reaction.](image)

For the charged mode the contributions from \( K^*_2(1430)K\pi \) and from \( K_1(1230)^\pm K^\mp, K_1(1400)^\pm K^\mp \) decaying to \( K^\pm\rho(770) \) are seen. The full PWA is needed to disintegrate the measured inclusive cross section to observed modes.

The BaBar Collaboration performs a combined PWA of these reactions [10] which allows to separate iso-scalar and iso-vector components of the cross sections for the quasi-two-body dominant \( K^*(892)^0K^0 \) and \( K^*(1430)K \) intermediate states. The iso-scalar component is dominated by the \( e^+e^- \rightarrow \phi(1680) \) resonance production. Again, large statistics allows to extract relatively small cross sections of \( e^+e^- \rightarrow \phi(1020)\eta \) and \( e^+e^- \rightarrow \phi(1020)\pi^0 \) reactions (see Fig. 5) which were not previously studied. These reactions are very good to search for the exotic states and BaBar demonstrates a hint of a possible state at about 1.5 GeV in the OZI suppressed \( \phi(1020)\pi^0 \) channel.
(Fig. 7(right)) with a structure at about 2.175 GeV. It is interpreted as a resonance with about 80 MeV width, later confirmed by BES and Belle experiments. The nature of this relatively narrow Y(2175) [22] state is not clear.

The two pions from the \( p \pi^+ \pi^- \eta \) reaction are the only ones seen in two-pion invariant mass (see Fig. 8(right)) with a structure at about 2.175 GeV. It is interpreted as a resonance with about 80 MeV width, later confirmed by BES and Belle experiments.

The nature of this relatively narrow Y(2175) [22] state is not clear.

The \( e^+e^- \rightarrow 2(\pi^+\pi^-)\pi^0 \) reaction has the largest cross section and has very distinctive \( \omega\pi^+\pi^- \) and \( \eta\pi^+\pi^- \) intermediate states seen in \( m(\pi^+\pi^-\pi^0) \) distribution of Fig. 8(left). They were studied before, but BaBar experiment [8] performed the most accurate measurement of the cross sections for these two channels. The two pions from the \( \eta\pi^+\pi^- \) reaction predominantly form \( \rho(770) \) while for the \( \omega\pi^+\pi^- \) reaction the \( f_0(980) \) signal is seen in two-pion invariant mass (see Fig. 8(right)) and, for the first time, the contribution of \( \omega f_0(980) \) was extracted and the cross section was measured (shown in Fig. 9(left)). The fit of the \( \omega\pi^+\pi^- \) cross section after subtraction of the \( \omega f_0(980) \) contribution can be used for more accurate information about \( \omega(1400) \) and \( \omega(1650) \) (see Fig. 10). The obtained parameters are in good agreement with those obtained from the \( \pi^+\pi^-\pi^0 \) channel and confirm an \( \omega(1650) \) width more narrow than what is listed in the previous edition of the PDG tables.

The \( e^+e^- \rightarrow 5 \) hadrons reactions

The BaBar detector studied \( 2(\pi^+\pi^-)\pi^0, 2(\pi^+\pi^-)\eta, K^+K^-\pi^+\pi^-\pi^0 \) and \( K^+K^-\pi^+\pi^-\eta \) reactions produced via ISR [8].

![Fig. 7](image_url) Left: The \( m(\pi^+\pi^-\pi^0) \) distribution for the \( e^+e^- \rightarrow \phi(1020)\pi^+\pi^- \) reaction. Right: The \( e^+e^- \rightarrow \phi f_0 \) cross sections measured with the BaBar detector.

![Fig. 8](image_url) Left: The \( m(\pi^+\pi^-\pi^0) \) distribution for the \( 2(\pi^+\pi^-)\pi^0 \) events. Right: The \( m(\pi^+\pi^-) \) distribution for all \( \omega\pi^+\pi^- \) events.

![Fig. 9](image_url) Left: The \( e^+e^- \rightarrow \omega f_0(980) \) cross section. Right: The two Breit-Wigner fit of \( \omega\pi^+\pi^- \) cross section with \( \omega f_0(980) \) contribution subtracted.

![Fig. 10](image_url) Left: The \( e^+e^- \rightarrow 2(\pi^+\pi^-)\pi^0 \) cross section and contribution from \( \omega\pi^+\pi^- \) (squares) and \( \eta\pi^+\pi^- \) (triangles) reactions. Right: The \( m(\pi^+\pi^-) \) (points) and \( m(\pi^+\pi^0) \) (histogram) distributions for \( 2(\pi^+\pi^-)\pi^0 \) events with \( \omega\pi^+\pi^- \) and \( \eta\pi^+\pi^- \) contributions excluded.

![Fig. 11](image_url) Left: The \( m(\eta\pi^+\pi^-) \) distribution for the \( 2(\pi^+\pi^-)\eta \) events. Right: The \( e^+e^- \rightarrow \eta(958)\pi^+\pi^- \) cross section and Breit-Wigner fit.

The \( \omega\pi^+\pi^- \) and \( \eta\pi^+\pi^- \) do not explain the total \( e^+e^- \rightarrow 2(\pi^+\pi^-)\pi^- \) cross section as shown in Fig. 10(left). When \( \omega\pi^+\pi^- \) and \( \eta\pi^+\pi^- \) contributions are excluded, the \( m(\pi^+\pi^-) \) and \( m(\pi^+\pi^0) \) distributions (see Fig. 10(right)) demonstrate equal number...
of charged and neutral $\rho(770)$ per event with the remaining three-pion mass around 1240 MeV/c$^2$ and about 400 MeV width. It is shown, that $e^+e^- \rightarrow 3\pi \pi$ cross section is dominated by $\rho(770)X(1240)$ production with $X(1240) \rightarrow \rho(770)\pi$ decay. The best candidates for $X(1240)$ are $\pi(1300)$ and $a_1(1260)$ [21]. The detailed PWA is needed for more definite statement. The $e^+e^- \rightarrow 2(\pi^+\pi^-)\eta$ was studied with the BaBar detector for the first time. Fig. 11(left) shows $m(\eta\pi^+\pi^-)$ distribution for these events, demonstrating contribution from $\eta(958)\pi^+\pi^- \rightarrow \eta(958)$ signal allows to extract $e^+e^- \rightarrow \eta(958)\pi^+\pi^- \eta$ cross section (Fig. 11(right)) (dominated by $\eta(958)\rho(770)$). The cross section has a resonance structure and can be interpreted as $\rho(2150)$ production. Another definite structure seen in Fig. 11(left) and shown in Fig. 12(left) was interpreted as production of $f_1(1285)\pi^+\pi^-$ intermediate state. After non-resonant background subtraction, the calculated $e^+e^- \rightarrow f_1(1285)\pi^+\pi^-$ cross section is shown in Fig. 12(right). A resonance structure also can be interpreted as $\rho(2150)$ production.

**Fig. 12.** The $m(\eta\pi^+\pi^-)$ distribution (a) for the $2(\pi^+\pi^-)\eta$ events. The $e^+e^- \rightarrow f_1(1285)\pi^+\pi^-$ cross section (b) and Breit-Wigner fit.

![Image](https://via.placeholder.com/150)

**Fig. 13.** The $m(\pi^+\pi^-\pi^0)$ (left) and $m(K^+K^-)$ (right) distributions for the $K^+K^-\pi^+\pi^-\pi^0$ events.

The cross sections for the $e^+e^- \rightarrow K^+K^-\pi^+\pi^-\pi^0$ reaction was measured by BaBar for the first time. The three-pion and two-kaon invariant masses are shown in Fig. 13. The signals from $\eta$ and $\omega$ are well seen (small signal from $\phi$) in three-pion mass distribution with strong $\phi$ signal in $m(K^+K^-)$ distribution. Fig. 14 shows the calculated cross sections for the $e^+e^- \rightarrow \phi\eta$ (left) and $e^+e^- \rightarrow \omega K^+K^-$ (right) subprocesses. The first one is in good agreement with obtained in the $\eta \rightarrow \gamma\gamma$ mode [10]. It is first measurement for the second process with possible structures, but the only significant one is $J/\psi \rightarrow \omega K^+K^-$ signal.

The cross sections for the $e^+e^- \rightarrow K^+K^-\pi^+\pi^-\eta$ reaction was also measured by BaBar for the first time. The cross section is small and the only significant signal observed was $e^+e^- \rightarrow \phi\eta(958)$ in the studied $K^+K^-\pi^+\pi^-\eta$ final state.

![Image](https://via.placeholder.com/150)

**Fig. 14.** The $e^+e^- \rightarrow \phi\eta$ (left) and $e^+e^- \rightarrow \omega K^+K^-$ (right) cross sections for the $K^+K^-\pi^+\pi^-\eta$ events.

### 3.7 The $e^+e^- \rightarrow 3(\pi^+\pi^-), 2(\pi^+\pi^-\pi^0)$ reactions

These reactions were studied before by several experiments but with almost 100 times smaller statistic and very large systematic uncertainties. The BaBar detector performed measurement of the six-pion $e^+e^-$ production [9] from the threshold to about 5 GeV using ISR events. The systematical uncertainty was dramatically reduced. One of the interesting observation in the $3(\pi^+\pi^-)$ was a presence of only one $\rho(770)^0$ per event in many possible $\pi^+\pi^-$ combinations. No other intermediate resonance signals were observed. For the $2(\pi^+\pi^-\pi^0)$ final state we also observed only one $\rho(770)^0$ or $\rho(770)^\pm$ per event with expected $1/2$ ratio.

![Image](https://via.placeholder.com/150)

**Fig. 15.** The $e^+e^- \rightarrow \omega\eta$ cross section (left) and contribution of $e^+e^- \rightarrow \omega\pi^+\pi^-\pi^0$ and $e^+e^- \rightarrow \omega\eta$ cross sections to all $e^+e^- \rightarrow 2(\pi^+\pi^-\pi^0)$ events (right).
In the $2(\pi^+\pi^-\pi^0)$ final state we observe the $\eta$ and $\omega$ signals in the $\pi^+\pi^-\pi^0$ mass distribution. Also a small fraction of events corresponds to a correlated production of $\eta$ and $\omega$. The $e^+e^- \rightarrow \omega\eta$ cross section was measured for the first time (Fig. 15(left)) and the resonance structure fitted with the Breit-Wigner function is assumed to be from $\omega(1650) \rightarrow \omega(782)\eta$ reaction. The $e^+e^- \rightarrow 2(\pi^+\pi^-\pi^0)$ and $e^+e^- \rightarrow 3(\pi^+\pi^-)$ cross sections have very similar energy behavior (see Fig. 16) and the ratio of these two cross section is close to uniform with $3.98\pm0.06\pm0.41$ value. We also observe a dip structure just blow 2 GeV in total six-pion cross sections which was first observed by FENICE [23] experiment and confirmed by FOCUS [24].

We fit this structure with the Breit-Wigner function fully coherent with smooth non-resonant background shown in Fig. 16. The structure has a mass of about 1.88 GeV/c$^2$ and a width of about 0.1 GeV (wider than that from FOCUS) and could be interpreted as a proton-anti-proton ground state.

4 Summary

The BaBar detector has an intensive program for study low energy $e^+e^-$ cross sections using ISR events. Numerous $e^+e^- \rightarrow$ hadrons cross sections have been measured with accuracy better than all previous direct $e^+e^-$ experiments. The large integrated luminosity provided by PEP-II collider and the excellent BaBar detector performance allow to study many multi-hadron final states and extract intermediate resonance structures which includes mesons ($\pi,K,D)$ and barions ($p,\Lambda,\Sigma$). The parameters of many known states ($\omega(1400),\omega(1650),\phi(1680)\ldots$) and new resonance candidates ($\rho(2150),X(1880)\ldots$) were measured with accuracy better than current table values. New resonances have been discovered via ISR: $Y(4260),Y(4320),Y(2175)$. But in many cases the internal structures are very complicated and sophisticated PWA is needed to extract coupling constants and parameters of seen resonances. It is a challenge for future studies.
