## GF measurement of HERD using HerdSoftware

Lorenzo Pacini,  
[lorenzo.pacini@fi.infn.it](mailto:lorenzo.pacini@fi.infn.it),

# MC Calorimeter in HerdSoftware (12/2019)

- ◆ 21 vertical layers, 21x21 crystals (for the big vertical layers), crystal side: 3 cm.
- ◆ gap || x = 0.8 cm, gap || y = 0.4 cm, gap || z = 0.4 cm, bigger gaps = 1.5 cm.

- ➔ Maximum x length =  $21 * (3 + 0.8) - 0.8 = 79 \text{ cm} = LX$
- ➔ Maximum y length =  $21 * (3 + 0.4) - 3 * 0.4 + 1.5 * 2 = 73.2 \text{ cm} = LY$
- ➔ Maximum z length =  $21 * (3 + 0.4) - 3 * 0.4 + 1.5 * 2 = 73.2 \text{ cm} = LZ$

# GGG particle generation validation.

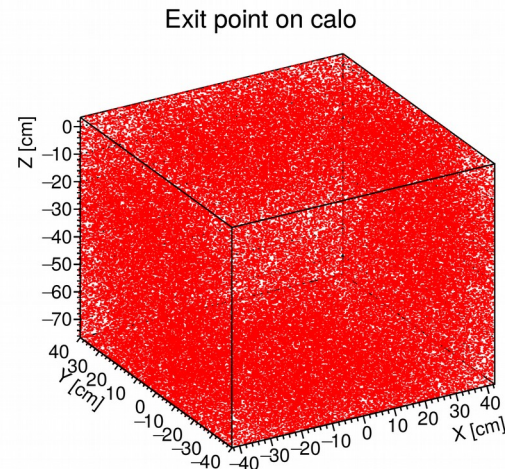

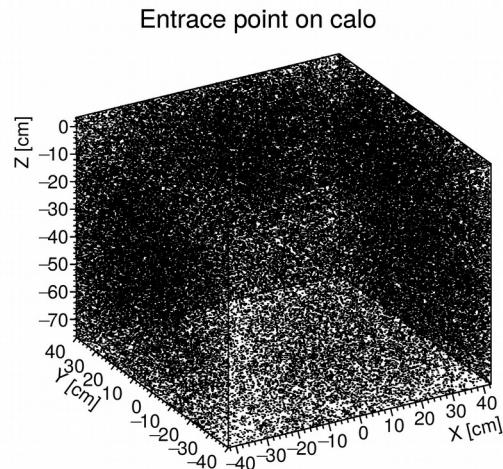

- ◆ Using the generator of GGS
  - simulation of a isotropic flux from a spherical surface, center = center of the Calo (0,0,-36.6), R=300 cm. geantino particles.
- ◆ Validation of the GGS generator:
  - using a sphere generation surface and a plane detector placed in different position inside the sphere.
  - The GF can be exactly computed using Sullivan formula and compared with the one extracted from the MC simulation.
  - For each configurations the GF is consistent with the expected.

**Generated particles which hit the planar detector**

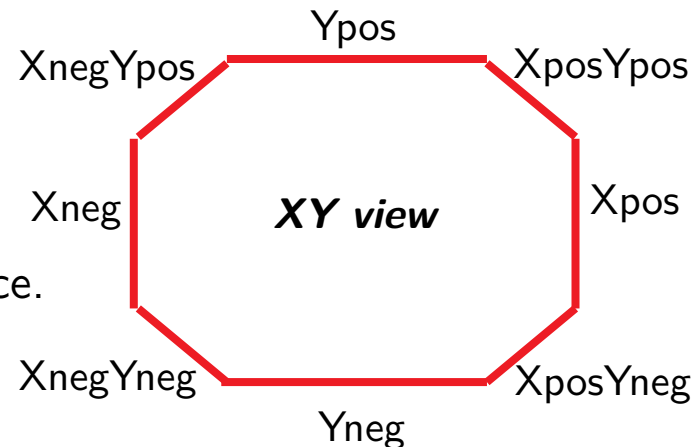

# GGG simulation acceptance check

- ◆ Since a large generation surface is used, a lot of generated particles are out of the detector acceptance.
- ◆ Acceptance check to simulate interesting particles only:
  - MC acceptance is larger than the true Calo acceptance.
  - The number of discarded particles is saved, thus it is possible to compute the geometrical factor of the detector.
- ◆ Selecting particles which hit an “Enlarged Calo”, which is a box =  $80 \times 80 \times 85$  cm<sup>3</sup>, excluding the bottom surface

# Calo acceptance definition

- ◆ 10 planes define the detector surface.
- ◆ A particle is in acceptance if:
  - The track intersects a Calo surface, excluding the bottom surface.
  - The track length in the Calo is  $>$  of a given threshold ( $X_0$ ).

Point on calo (MC track)

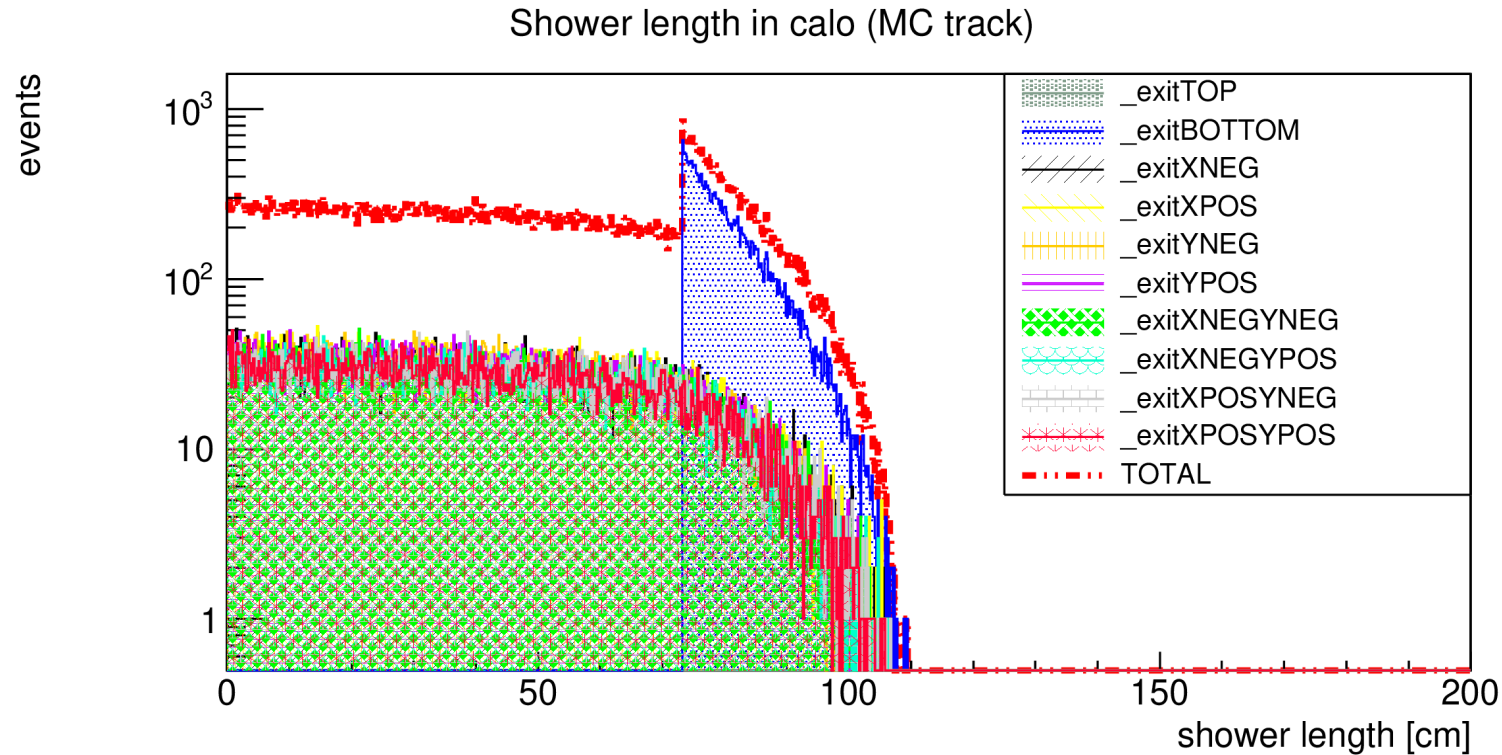

Exit point on calo (MC track)

# Track length for particle from the TOP

- ◆ Only TOP surface activated as entrance surface.

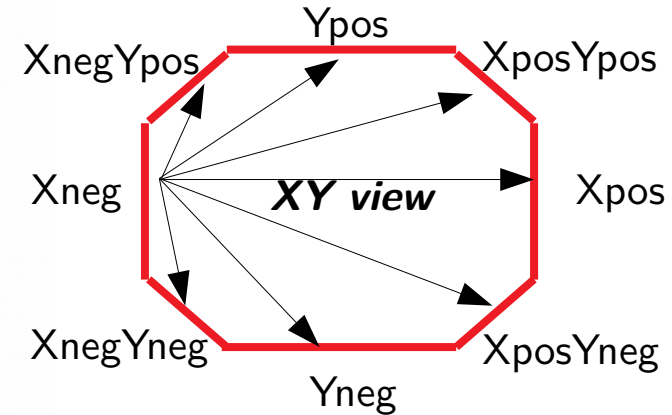

- ◆ The probability to get long track length is big if the exit point is in the bottom surface

# Track length for particle from XNEG

- ◆ Only XNEG surface activated as entrance surface.

Shower length in calo (MC track)

- ◆ Exit point in XPOS translates in big track length.

# Track length for all the particle

- ◆ All the entrance surface are excluding the BOTTOM

Shower length in calo (MC track)

- ◆ The distribution is very complicated since it is the sum of all the configuration.

## GF in function of the track length

- ◆ Testing the acceptance with different minimum track length configuration in 4 cases.
- ◆ Track length in cm should be converted in shower length in X0.
- ◆ The true computation of the track length in X0 depends on the position of each cubes:
  - Now an approximation is used:
    - $\text{Track\_X0} = \text{Track\_cm} * \text{MeanActiveFraction} * \text{LYSO\_X0}$
    - $\text{LYSO\_X0} = 1.1 \text{ cm}$
    - $\text{MeanActiveFraction} = 0.581323659$ .
  - Exact calculation will be soon integrated in HerdSoftware (see Jorge C. talk).

## Tested geometric configurations

- ◆ Main purpose: test the impact of the lateral surfaces with respect to the total acceptance
- ◆ We focus on the Calo “corners” since looking at the mechanical structure of the calorimeter (preliminary), the corners are covered with a lot of material.
- ◆ Is not clear if the tracker can completely cover the corner.

# Geometrical factor vs track length

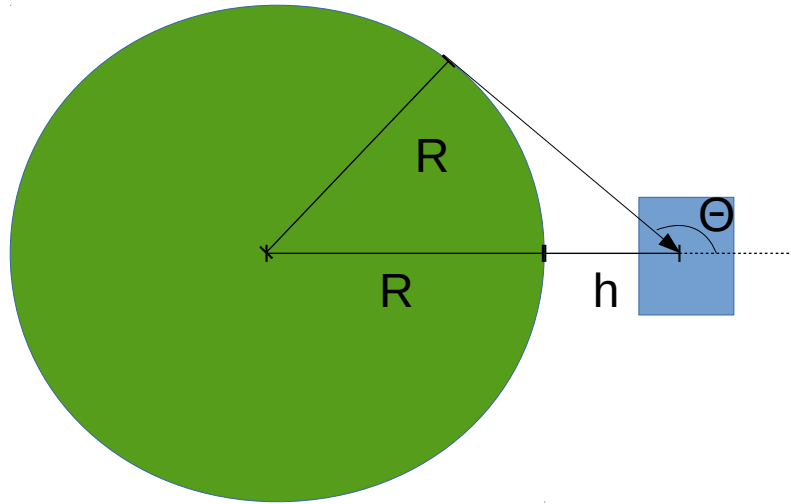

GF vs track length in calo

- ◆ With a cut in between 30 and 40  $X_0$  the total GF is  $\sim 3.5 \text{ m}^2\text{sr}$ . In this config. If we reject particles entering from the corners we lost about  $1.5 \text{ m}^2\text{sr}$ .

## Earth shadow and zenith angle cut.

- ◆ The Earth could stop particle arriving below the horizon (polar angle  $A > 90$  deg).
- ◆ Rough approximation: the Earth limits the maximum polar angle:

$$\Theta_E = \frac{\pi}{2} + \arccos\left(\frac{R_E}{R_E + h}\right)$$

$$R_E \sim 6370 \text{ km}$$

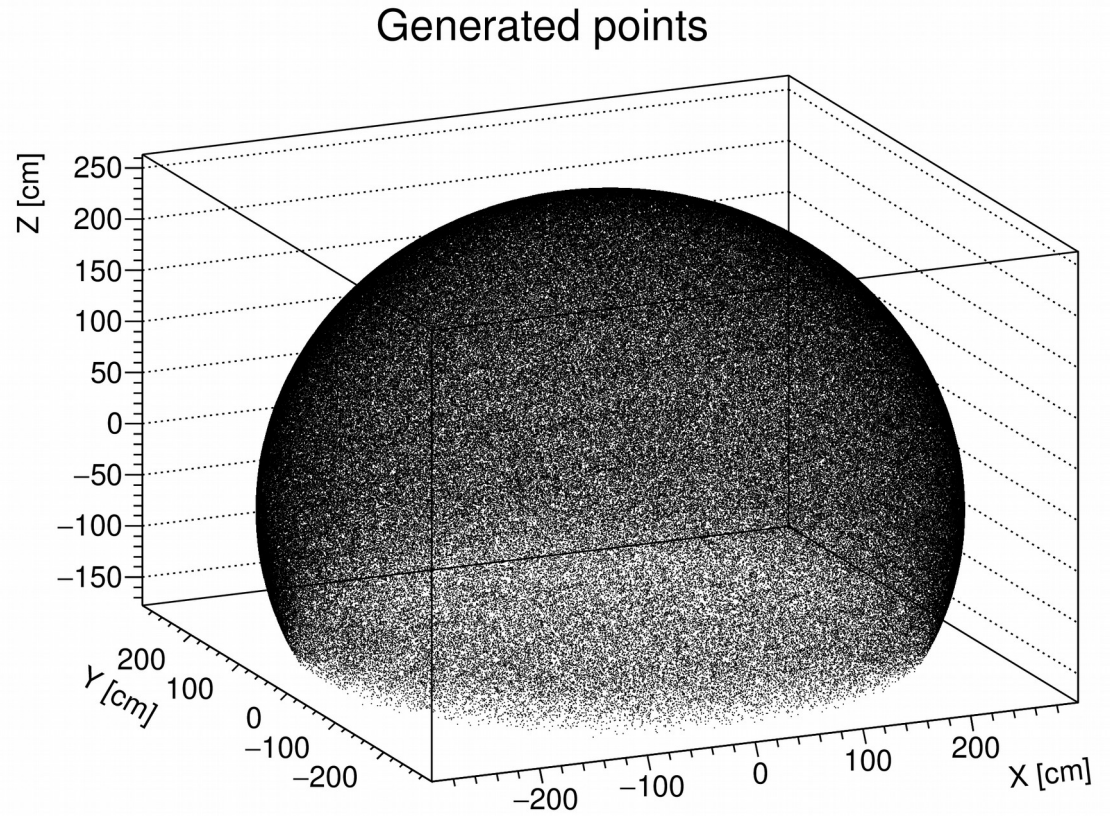

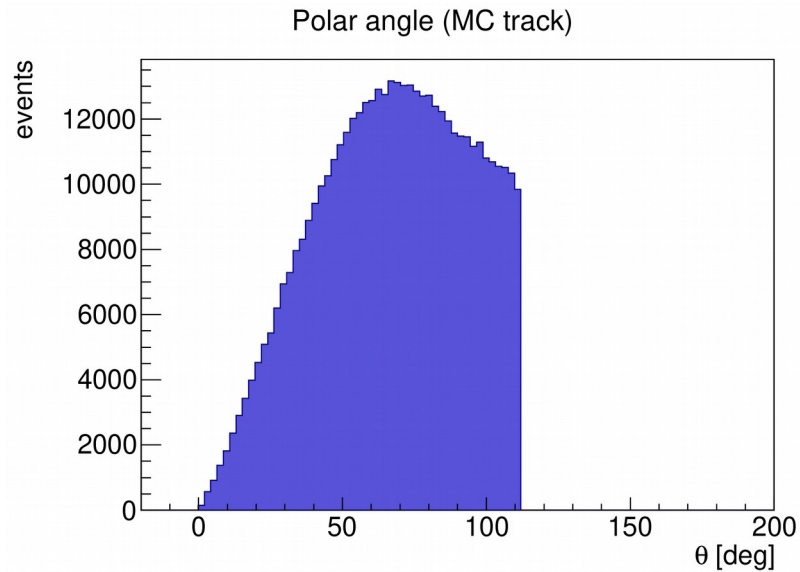

$$H \sim 500 \text{ km}$$

$$\Theta_E \sim 112 \text{ deg}$$

- ◆ For Herd  $\Theta_{\max} = 112^\circ$  since the  $\Theta$  angle is defined as  $180 - \text{polar}$ , thus the downward direction has  $\Theta = 0$ .

# Polar angle cut checks

- ◆ Check the polar angle and the starting point of the track after the polar angle cut

# Geometrical factor vs polar angle cut

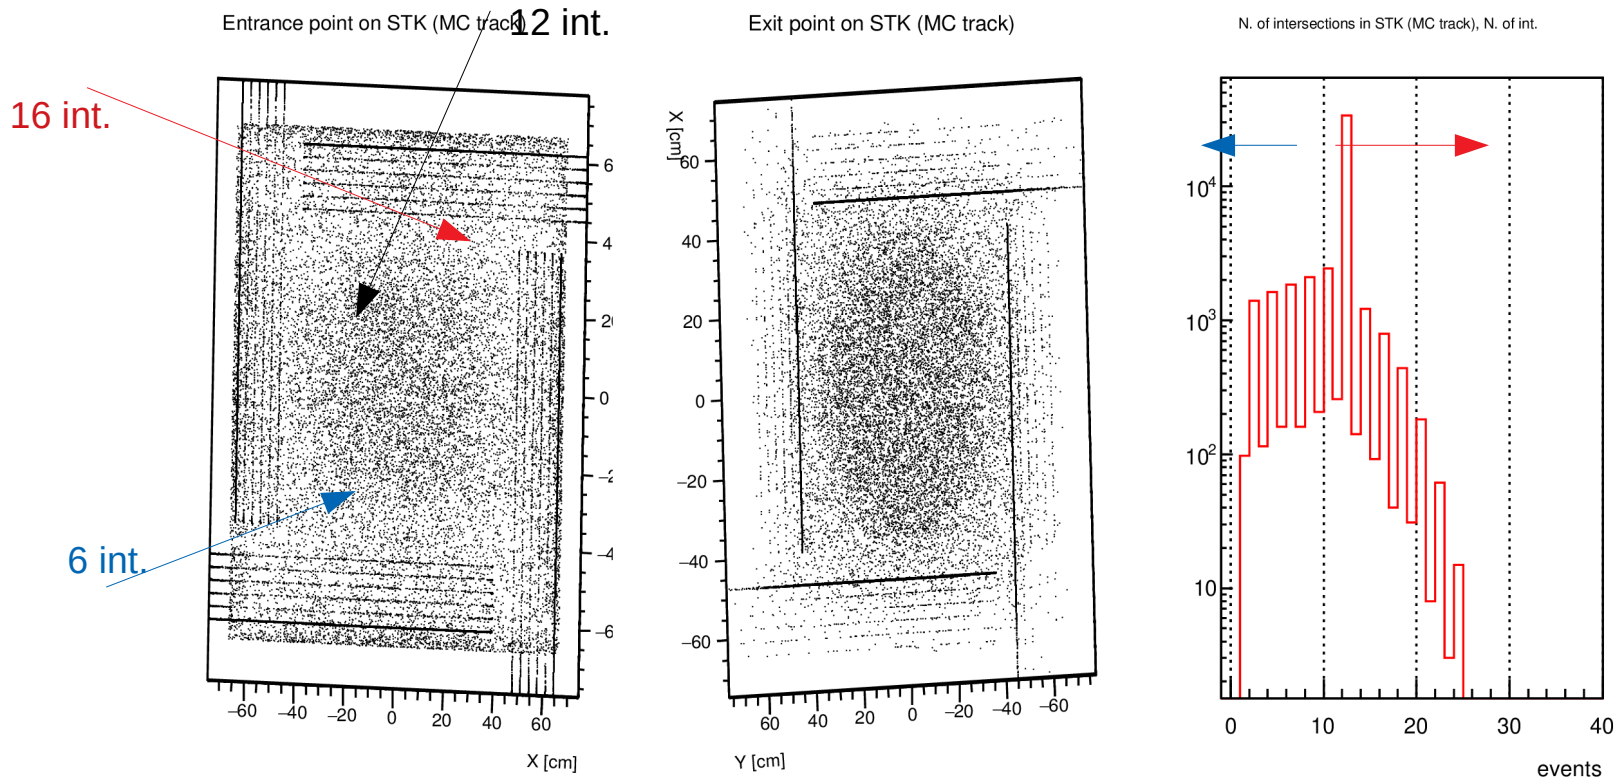

GF vs track length in calo

- ◆ The blue line is the maximum GF that we can obtain if we consider the Earth shadow. If the calorimeter is surrounded by a lot of structure the black line should be more realistic.

# Entrance and exit point in STK

- ◆ Taking into account the current STK geometry: The intersections between the true particle track and the STK are computed. Particle with the number of intersection below a given threshold are rejected.

# Entrance and exit point in STK

- ◆ Using 112 polar angle cut, using all the Calo faces (excluding bottom), requiring a different number of intersections of the MC track with the STK layers

GF vs track length in calo

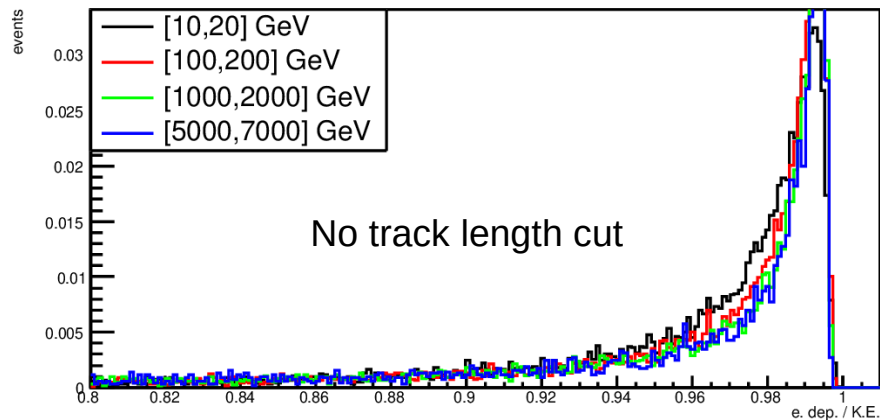

# First simulations of spectra with HerdSoftware

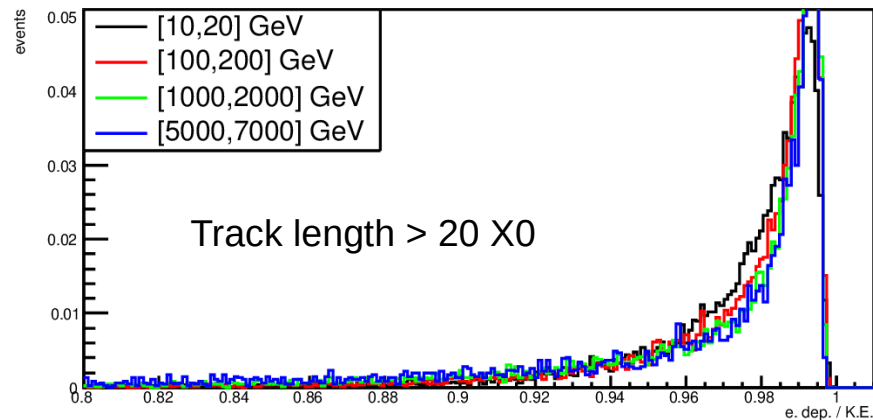

- ◆ Using HerdSoftware baseline geometry we simulated
  - 1 M events of electrons, from 10GeV to 10 TeV,
  - $E^{-1}$  spectrum,
  - Spherical generation, with the MC acceptance check.
- ◆ The GGS output is digitized and the variables used for the acceptance computation are also added.
  - First time that this is done for a production!
  - Should be validated in next months.
  - Proton between 10GeV and 100 TeV are also produced to start the study of e/p rejection factor.
- ◆ First look of electrons, energy resolution in function of the track length.

# E. dep. / kinetic energy for electrons

E. dep. / K.E.

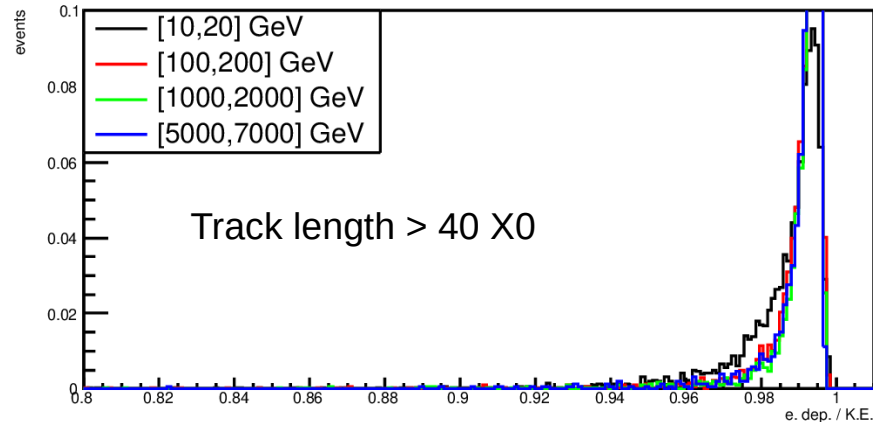

E. dep. / K.E.

E. dep. / K.E.

E. dep. / K.E.

# Electron energy resolution.

## Energy resolution vs track length

## Mean e. dep. fraction vs track length

## Conclusion

- ◆ The GF is measured using GEANT4 MC and genatino generated from a sphere.
- ◆ A requirement about the track length in the Calo is added to select well contained EM showers.
- ◆ The final results discussed in this presentation takes into account also the STK (with the current geometry):
  - for track length  $> 30X_0$ , a number of intersections of the MC track with STK layers  $\geq 10$ , a cut on the polar angle  $> 112$  deg, **the GF is  $\sim 2.5$  m<sup>2</sup>sr**, which is consistent with previous measurement.
- ◆ The algorithms used for this analysis were recently added to HerdSoftware.
- ◆ First look @ electron MC (no passive material is simulated so far):
  - we can get an energy resolution  $< \sim 2\%$  from 10 GeV to 5 TeV with 30  $X_0 \rightarrow 2.5$  m<sup>2</sup>sr
- ◆ To do: protons, FIT, SCD, update track length algo, .... a lot of work!
