Outline

- Computational Perspective of Lattice QCD
- Brief Introduction to Hybrid Monte Carlo
- Brief Introduction to Multigrid Method
- Hasenbusch Preconditioning Method
- Summary

Computational Perspective of Lattice QCD

- Lagrangian formulation

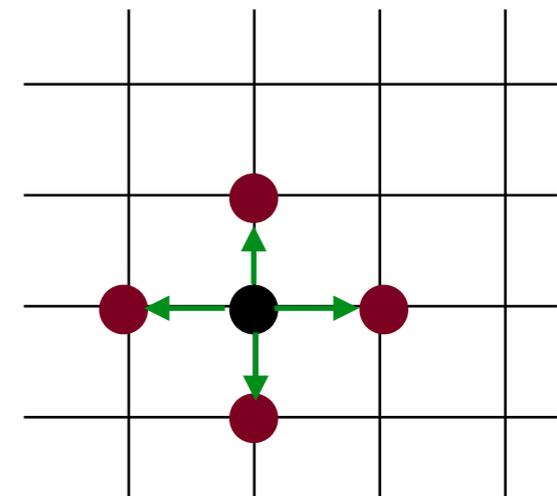

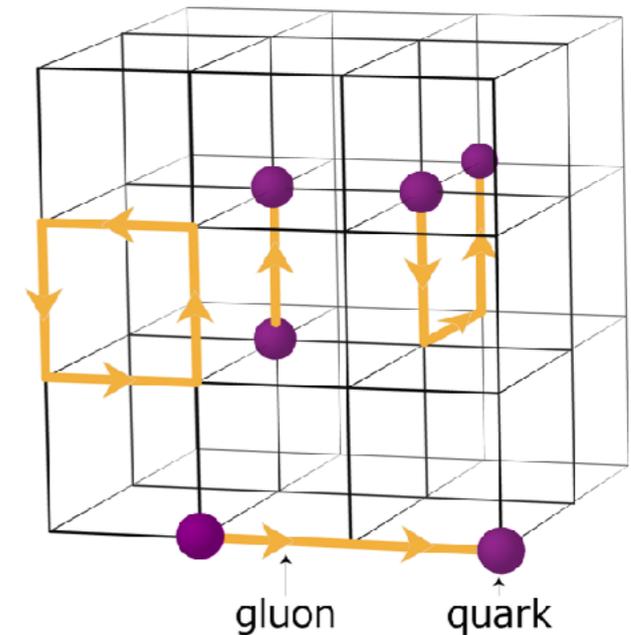

- Discretized spacetime, finite volume: **finite d.o.f**
- Computer simulation: **Markov Chain Monte Carlo, Importance Sampling.**

- LQCD need supercomputer / cluster to simulate

- $$D_{x,y} = \sum_{\mu} (1 - \gamma_{\mu}) U_{\mu}(x) \delta_{x+\hat{\mu},y} + (1 + \gamma_{\mu}) U_{\mu}(x - \hat{\mu})^{\dagger} \delta_{x-\hat{\mu},y}$$

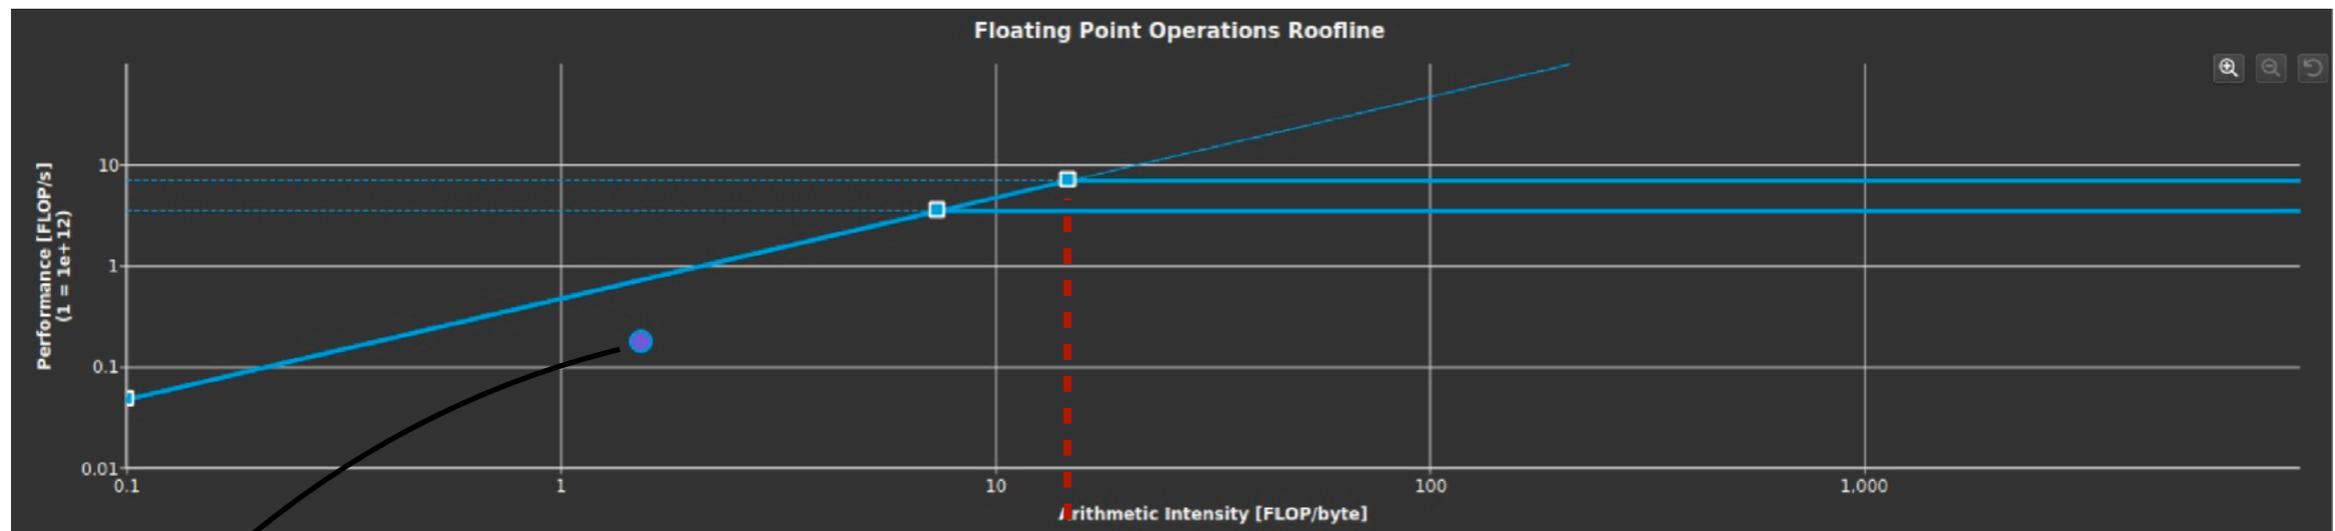

- Four dimensional 8(9) point stencil operation

- HPC(High Performance Computing)
+
HTC(High Throughput Computing)

Computational Perspective of Lattice QCD

- Roofline model (by Berkeley Lab)
- A performance analysis and optimization model

Memory bound

Compute bound

- Lattice QCD Wilson dslash AI (Arithmetic Intensity) ~ 1 Flops/Byte
- Memory bound
- Optimization strategy: increase the AI

Brief Introduction to Hybrid Monte Carlo

- Euclidean path integral on lattice

$$\langle O \rangle = \frac{1}{Z} \int \mathcal{D}U \mathcal{D}\bar{\psi} \mathcal{D}\psi O[U, \bar{\psi}, \psi] e^{-S_g - S_f}$$

- S_g gauge action, $S_f = \bar{\psi} D \psi$ fermion action, D Dirac operator
- Integrated over Grassmann variable $\bar{\psi}, \psi$

$$\langle O \rangle = \frac{1}{Z} \int \mathcal{D}U O'[U] \det D e^{-S_g}$$

- $\gamma_5 D \gamma_5 = D^\dagger \rightarrow \det D^\dagger = \det D$, $\det D$ **is real**
- Two flavor degenerate $N_f = 2$, $\det D_u \det D_d = \det D^2 = \det D^\dagger D \geq 0$
- **Markov Chain Monte Carlo**: $\frac{1}{Z} \det D^\dagger D e^{-S_g} \geq 0$ as probability distribution
- Note: for odd number of flavors
e.g. $N_f = 1$, $\det D = \det \sqrt{D^\dagger D}$, use **RHMC** algorithm
- **Focus on $N_f = 2$ algorithm in this talk**

Brief Introduction to Hybrid Monte Carlo

- $\det D$ is nonlocal and nearly impossible to evaluate directly
- Rewrite $N_f = 2$ fermion determinant $\det D^\dagger D$ as bosonic pseudo-fermion field

$$\langle O \rangle = \frac{1}{Z} \int \mathcal{D}U O[U] \det D^\dagger D e^{-S_g} = \frac{1}{Z} \int \mathcal{D}U \mathcal{D}\bar{\phi} \mathcal{D}\phi O[U] e^{-S_g - S_{pf}}$$

- With pseudo-fermion action $S_{pf} = \phi^\dagger (D^\dagger D)^{-1} \phi$
- Hybrid Monte Carlo(HMC): Molecular Dynamics(MD) + Metropolis Accept/Reject

▶ Introduce conjugate momentum $P \in su(3)$ of gauge link U

▶ Construct Hamiltonian $H = \frac{1}{2}P^2 + S = \frac{1}{2}P^2 + S_g + S_{pf}$

▶ Solve Hamiltonian equation numerically

$$\dot{P} = -\frac{\delta H}{\delta U} = -\frac{\delta S_g}{\delta U} - \frac{\delta S_{pf}}{\delta U} = F_g + F_f$$

$$\dot{U} = \frac{\delta H}{\delta P} = P$$

gauge force
easy to evaluate

fermionic force
time consuming $(D^\dagger D)^{-1}$

▶ Metropolis Accept/Reject with probability $P_{acc} = \min(1, e^{-\Delta H})$

Basic HMC Algorithm

1. Start from some initial/random gauge field U

→ 2. Generate momentum field $P \sim e^{-\frac{1}{2}P^2}$

3. Generate pseudo-fermion field $\phi \sim e^{-\phi^\dagger(D^\dagger D)^{-1}\phi}$

(1) Generate gaussian random variable $\eta \sim e^{-\eta^\dagger\eta}$, then $\phi = D^\dagger\eta$

4. Compute Hamiltonian/Energy H with U

5. MD trajectory evolution with e.g. leapfrog integrator

(1) Trajectory length τ_0 , integration step N , step size $\epsilon = \frac{\tau_0}{N}$

(2) Leapfrog integration

$P(0) \rightarrow P(\epsilon/2) \rightarrow P(\epsilon)$	every momentum P update step need to solve $(D^\dagger D)^{-1}$!
$U(0) \longrightarrow U(\epsilon)$	

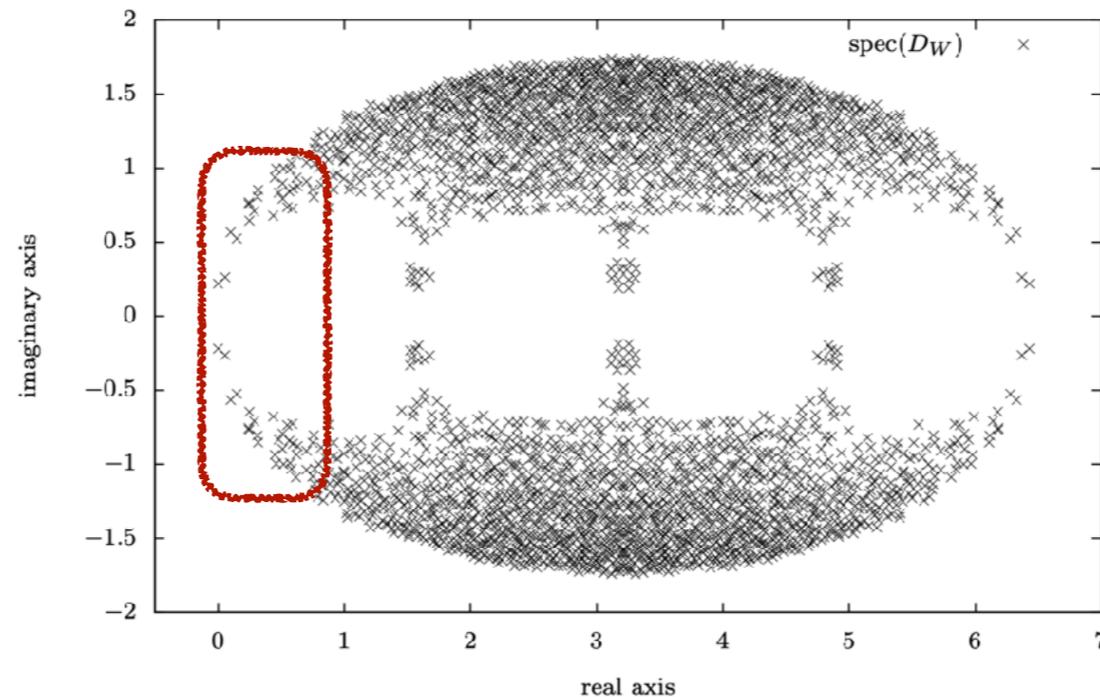

6. Compute Hamiltonian/Energy H' with new gauge field U'

7. Accept/Reject U' with $P_{acc} = \min(1, e^{-\Delta H})$, $\Delta H = H' - H$

— 8. if(Accept): next trajectory from U' ; if(Reject): start from old U

Iterative Krylov Subspace Solvers

- Most time consuming part in LQCD: propagator D^{-1} / HMC $(D^\dagger D)^{-1}$

[J. Brannick *et.al.* **Numer.Math.** 132 (2016) no.3, 463-490]

- Wilson like fermion break chiral symmetry
- Near zero mode of Dirac operator even for massive quark
- Problems of simulating light quarks
 - ▶ Regular single-grid Krylov subspace solvers -> critical slowing down: multigrid method 😊
 - ▶ Fermionic force F_f blow up -> MD integration unstable: need new algorithm 😭

Even-Odd Preconditioning

- Group lattice sites into even-odd ($\sum x_i$ even or odd)

$$D = \begin{pmatrix} A_{ee} & D_{eo} \\ D_{oe} & A_{oo} \end{pmatrix}$$

- Asymmetric even-odd precondition

$$D = \begin{pmatrix} 1 & 0 \\ D_{oe}A_{ee}^{-1} & 1 \end{pmatrix} \begin{pmatrix} A_{ee} & 0 \\ 0 & A_{oo} - D_{oe}A_{ee}^{-1}D_{eo} \end{pmatrix} \begin{pmatrix} 1 & A_{ee}^{-1}D_{eo} \\ 0 & 1 \end{pmatrix}$$

$$\det D = \det A_{ee} \det \hat{D}_a = \det A_{ee} \det (A_{oo} - D_{oe}A_{ee}^{-1}D_{eo})$$

- Symmetric even-odd precondition

$$D = \begin{pmatrix} A_{ee} & 0 \\ 0 & A_{oo} \end{pmatrix} \begin{pmatrix} 1 & A_{ee}^{-1}D_{eo} \\ A_{oo}^{-1}D_{oe} & 1 \end{pmatrix}$$

$$\det D = \det A_{ee} \det A_{oo} \det \hat{D}_s = \det A_{ee} \det A_{oo} \det (1 - A_{oo}^{-1}D_{oe}A_{ee}^{-1}D_{eo})$$

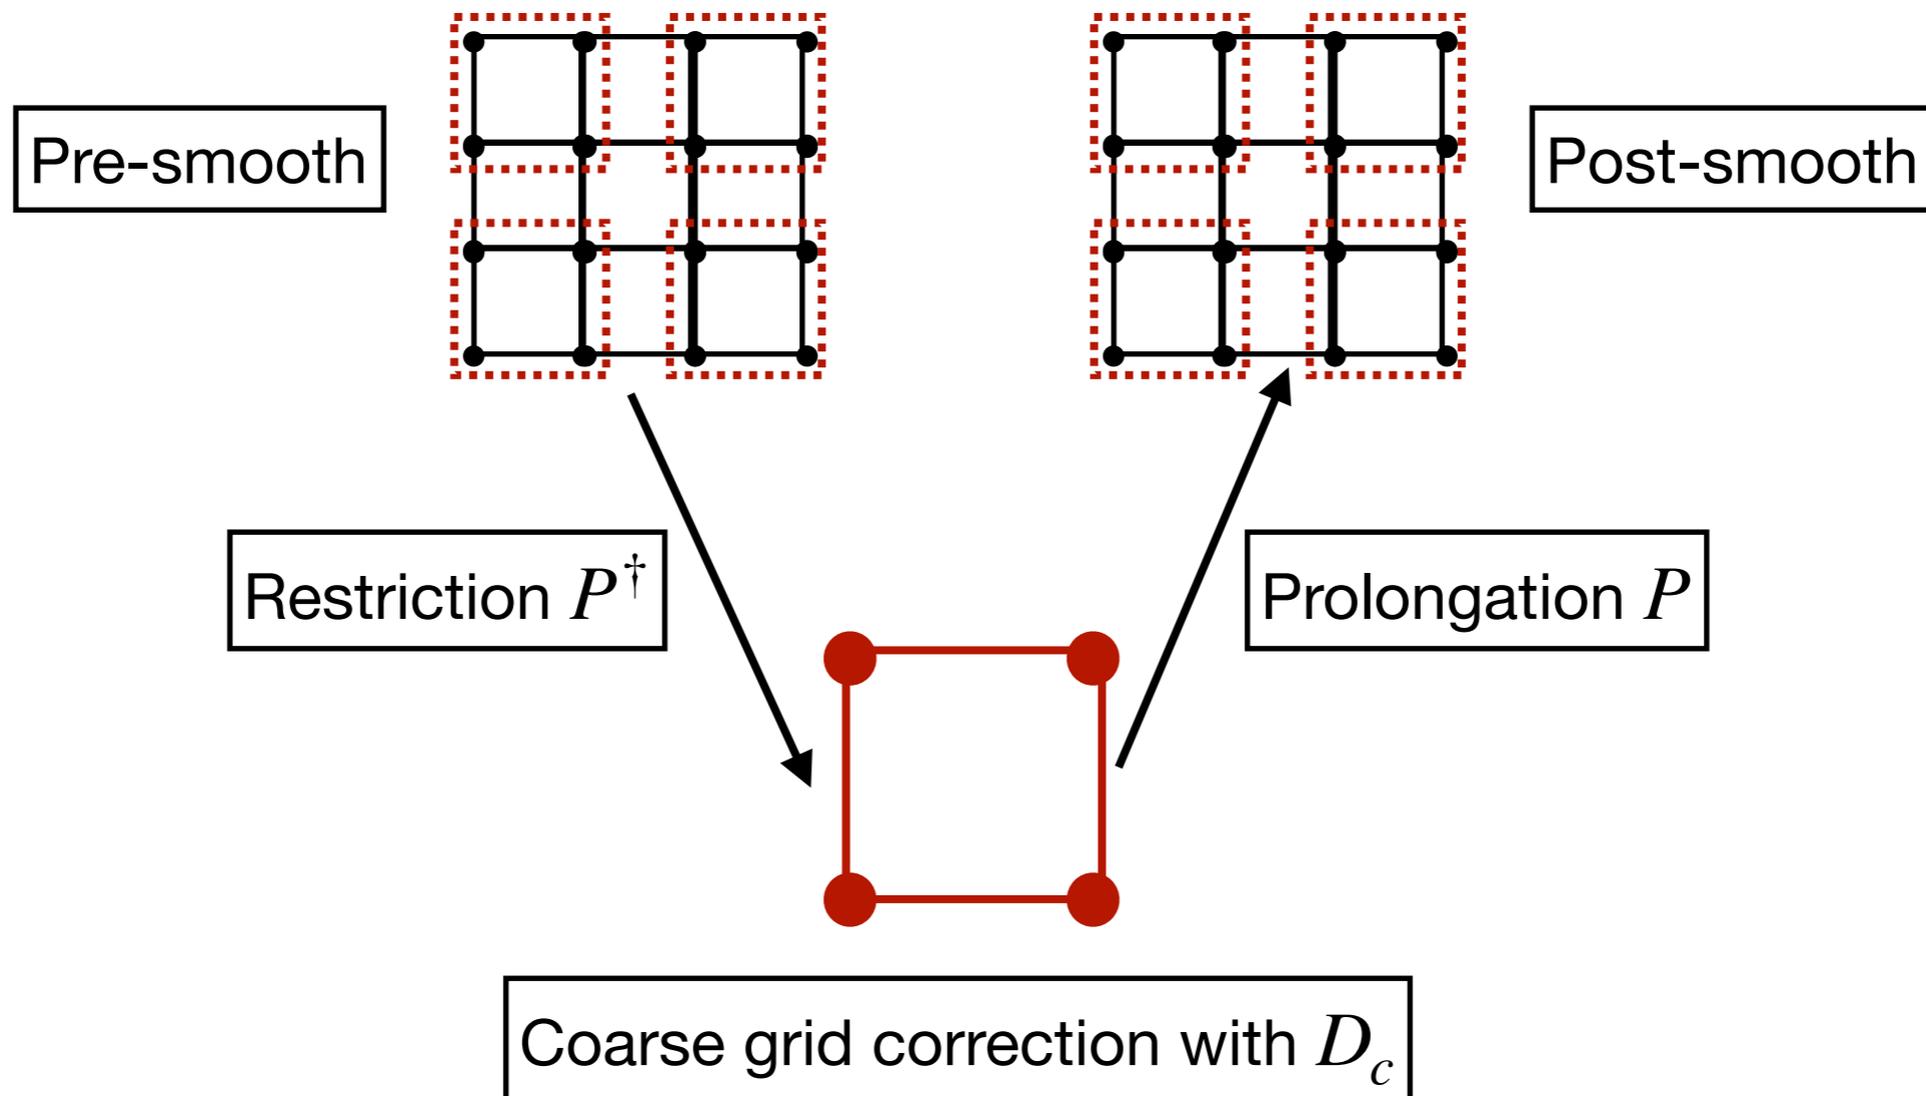

- With preconditioned operator \hat{D}_a and \hat{D}_s
 - ▶ Better conditioned linear system -> speed up in inversion D^{-1} (e.g. propagator)
 - ▶ Factorized pseudo-fermion action in HMC -> more efficient simulation

Brief Introduction to Multigrid Method

- Motivated from multigrid method in solving partial differential equation
- Deal with high and low frequency mode on fine and coarse grid
- **Stochastic** nature of gauge field -> adaptive aggregation based algebraic multigrid [R. Babich, **Phys.Rev.Lett.**105:201602,2010]
- Capture low frequency mode (slow to convergence) with near null vectors
- Multigrid setup
 - ▶ Generate near null vector with $Dv_i = 0$
 - ▶ Construct prolongator P and restrictor R from v_i
 - ▶ Create coarse operator with Galerkin projection $D_c = RDP$, usually choose $R = P^\dagger$

Brief Introduction to Multigrid Method

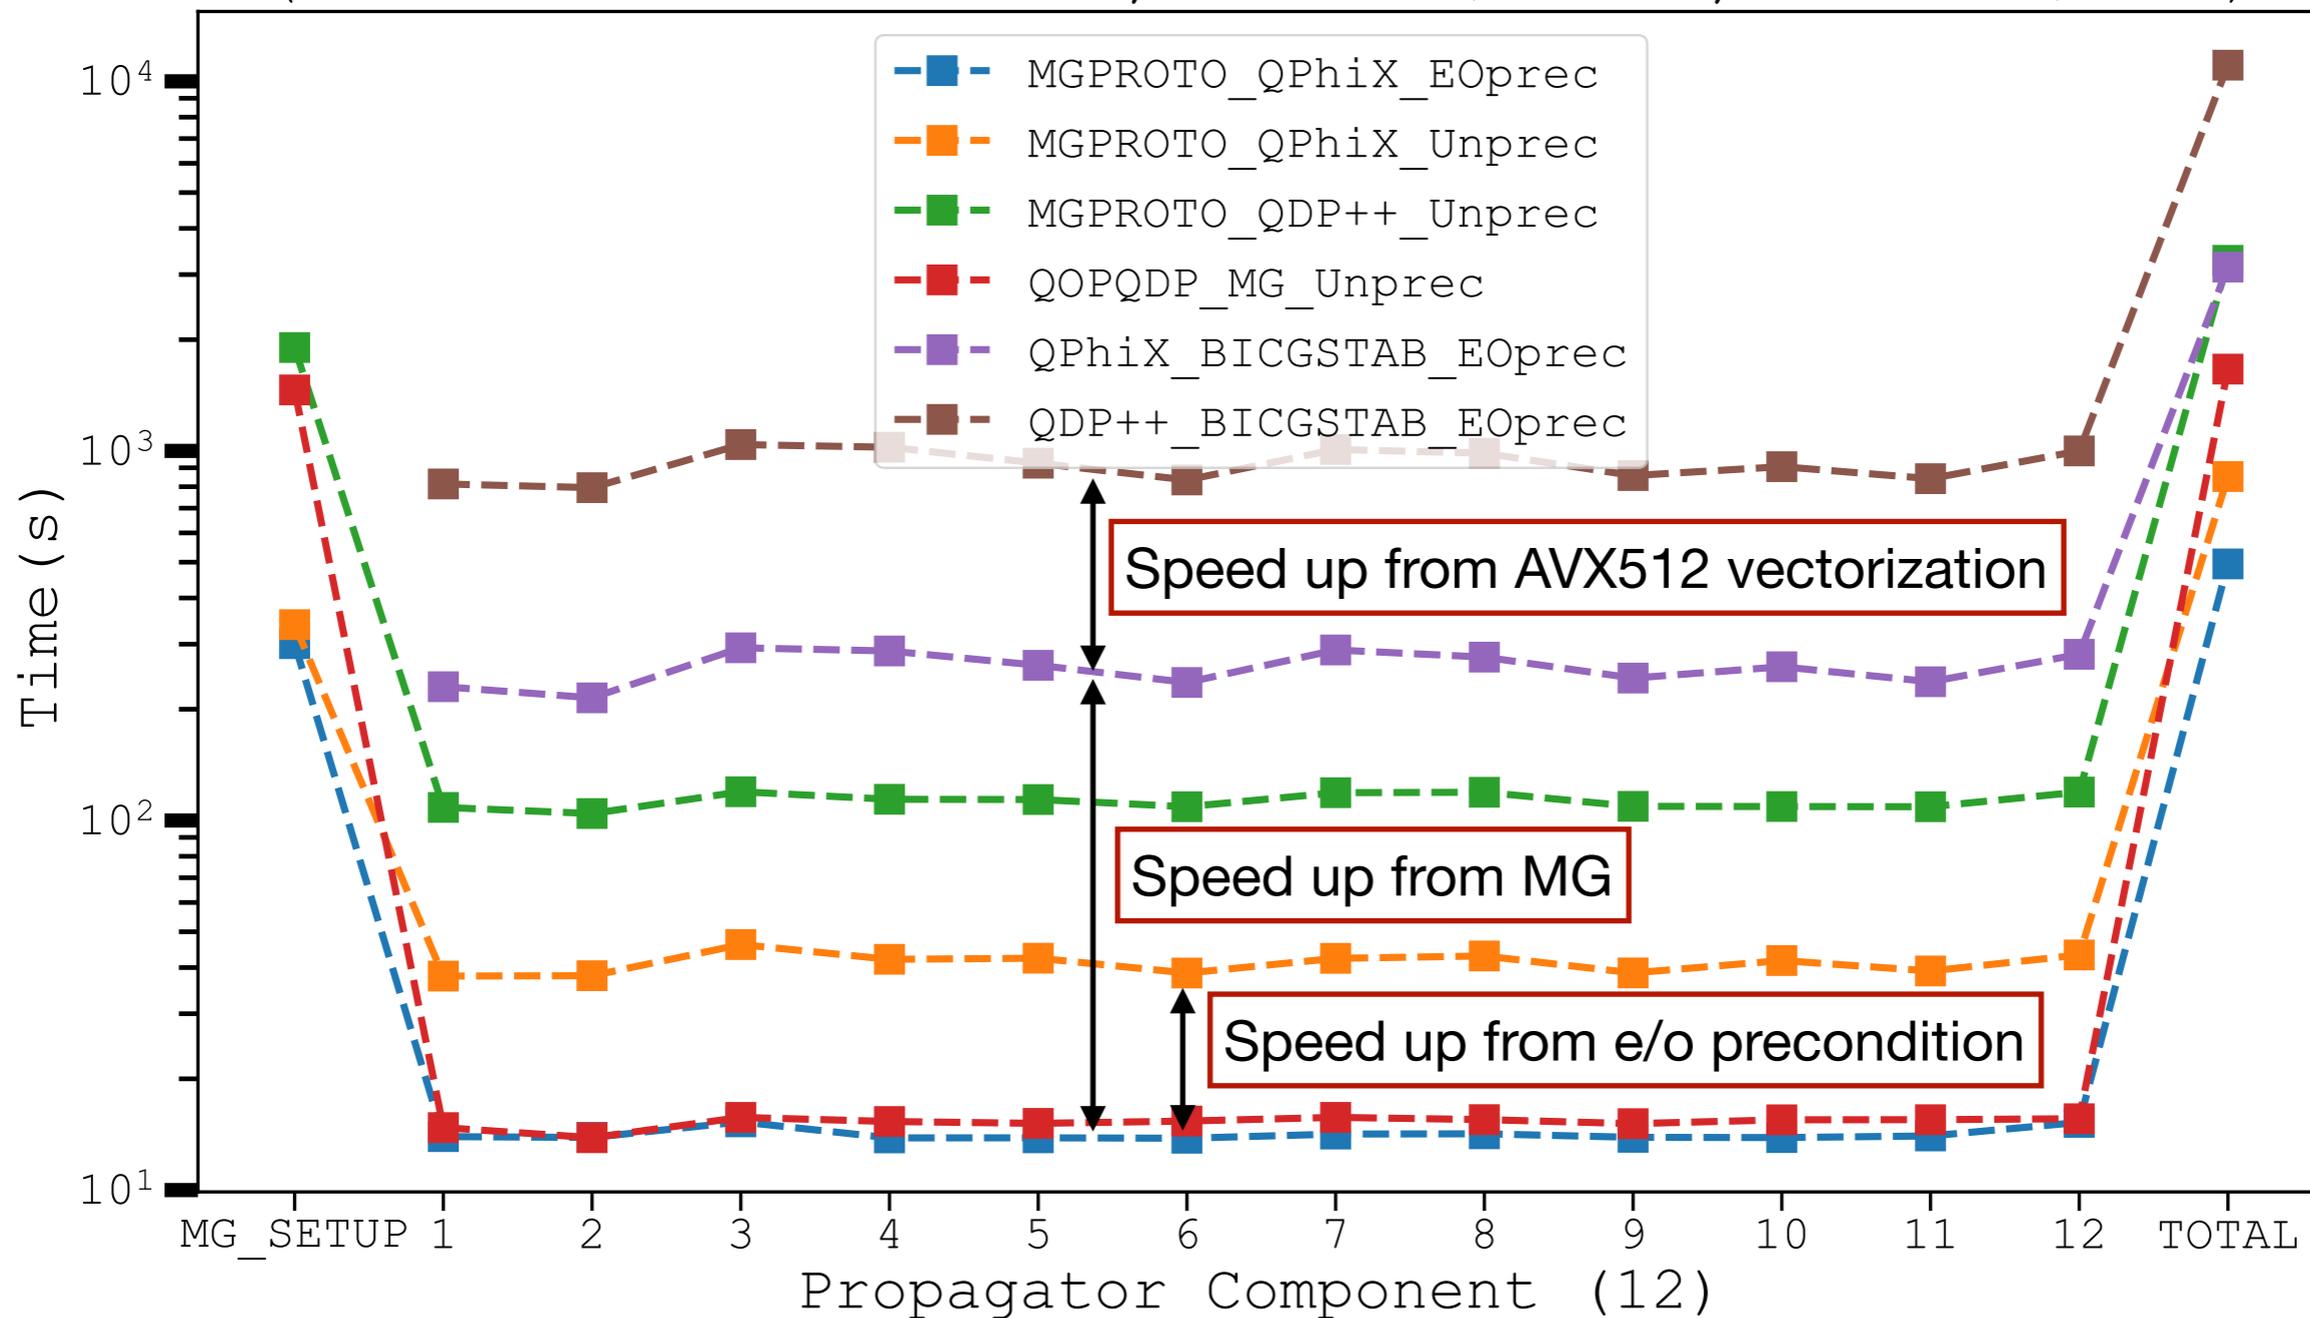

- Multigrid V-cycle (can be used as solver itself)

- More efficient choice: use MG as **preconditioner** of Krylov solver (e.g. GCR, FGMRES) and solve the coarse grid **recursively** (K-cycle)

MG Use Case: Quark Propagator

$64^3 \times 192, m_\pi \sim 310$ MeV @ 14 Frontera Cascade Lake Node
(Intel Xeon Platinum 8280, 28 cores/socket, 56 cores/node)

MG Use Case: Distillation Method

- Quark field smearing scheme

- Factorize operators construction and propagator computation
- Large operator set can be used to do the GEVP analysis
- Compute disconnected diagram easily

- Large amount of $Dx = b$

- On every configuration $N_t \times N_{spin} \times N_{vec}$
- Very suitable for MG especially at light quark (reuse MG setup)

- step 1: Laplace eigenvectors V

- step 2: perambulator

$$\tau_{\alpha\beta}(t', t) = V^\dagger(t') D_{\alpha\beta}^{-1}(t', t) V(t)$$

- step 3: elemental

$$\Phi_{\alpha\beta}(t) = V^\dagger(t) [\Gamma(t)]_{\alpha\beta} V(t)$$

- step 4: correlation functions

$$\begin{aligned} C_M^{(2)}(t', t) &= \langle \bar{d}(t') \Gamma^B(t') u(t') \cdot \bar{u}(t) \Gamma^A(t) d(t) \rangle \\ &= \text{Tr} [\Phi^B(t') \tau(t', t) \Phi^A(t) \tau(t, t')] \\ &\quad + \text{Tr} [\Phi^A(t) \tau(t, t)] \text{Tr} [\Phi^B(t') \tau^\dagger(t', t')] \end{aligned}$$

- $N_f = 2, 16^3 \times 128, m_\pi = 350 \text{ MeV}, N_{conf} = 7000, N_{vev} = 70$
 - 2 month * 100 V100 GPU on IHEP cluster, ~140 TB storage
 - On Huawei Kunpeng 920 (Arm), MG is 3.6x vs. BiCGStab [Wei sun, Yujiang Bi, ACAT 2021]

MG Use Case: HMC

- Most time consuming part in HMC $(D^\dagger D)^{-1}$
- Problems of near zero mode of Dirac operator
 - ▶ Slow to convergence -> solved by MG
 - ▶ Large fluctuation in fermionic force term
- **Hasenbusch mass preconditioning:** [M. Hasenbusch, Phys.Lett. B519 (2001) 177-182]
 - ▶ factorize fermion determinant

$$\det D = \frac{\det D(m_0) \det D(m_1)}{\det D(m_1) \det D(m_2)} \dots \det D(m_n)$$

force term can be fine tuned

easy to solve

- **HMC + MG**
 - Reuse / refresh MG setup after several MD integration
 - Multiple time scale MD integration scheme

MG Use Case: HMC

- Based on these algorithms, we have generated several ensembles
- $N_f = 2$ anisotropic clover (by 宫明)

Ensemble	$L^3 \times T$	β	a_s (fm)	ξ	N_{cfg}	$m_{J/\psi}$ (MeV)
I	$16^3 \times 128$	2.8	0.1026	5	~ 7000	2743(1)

Twisted Hasenbusch Preconditioning

[Wei Sun, Balint Joo, Kate Clark, ECP report]

- Problems of near zero mode of Dirac operator
 - ▶ Slow to convergence -> solved by multigrid
 - ▶ Large fluctuation in fermionic force term
- Mass ratio method: directly set the bare quark mass
 - ▶ Easy to implement, but still with near zero mode

$$\det D = \frac{\det D(m_0) \det D(m_1)}{\det D(m_1) \det D(m_2)} \dots \det D(m_n)$$

- Twist ratio method: add a twist μ to Wilson/Clover Dirac operator D
- $M(\mu) = \hat{D}_s + i\mu\gamma_5 A_{oo} = 1 - A_{oo}^{-1} D_{oe} A_{ee}^{-1} D_{eo} + i\mu\gamma_5 A_{oo}$, $M(\mu = 0) = D$
- $M^\dagger(\mu)M(\mu) = \hat{D}_s^\dagger \hat{D}_s + \mu^2 A_{oo}^2$, eigenvalue bounded from below

$$\det D = \frac{\det M(0) \det M(\mu_1)}{\det M(\mu_1) \det M(\mu_2)} \dots \det M(\mu_n)$$

- Other approaches: twisted mass reweighting and exponential clover by M. Luscher [Comput.Phys.Commun. 184 (2013), Comput.Phys.Commun. 255 (2020)]

Twisted Hasenbusch Preconditioning: test

- Clover, $N_f = 2 + 1$, $64^3 \times 128$, $m_\pi \approx 170 \text{ MeV}$, $\beta = 6.3$
- 512 Summit V100 GPUs
- 50 trajectories
- Multiple time scale force gradient MD integrator, $\tau_0 = 0.707$
- MG solver relative residue: MD ($1e-11$), Accept/Reject($1e-12$)
- Mass-Ratio parameter:

$$\triangleright \frac{[-0.2416]}{[-0.2400]} \times \frac{[-0.2400]}{[-0.2320]} \times \frac{[-0.2320]}{[-0.2180]} \times \frac{[-0.2180]}{[-0.1870]} \times [-0.1870]$$

$F1$

$F2$

$F3$

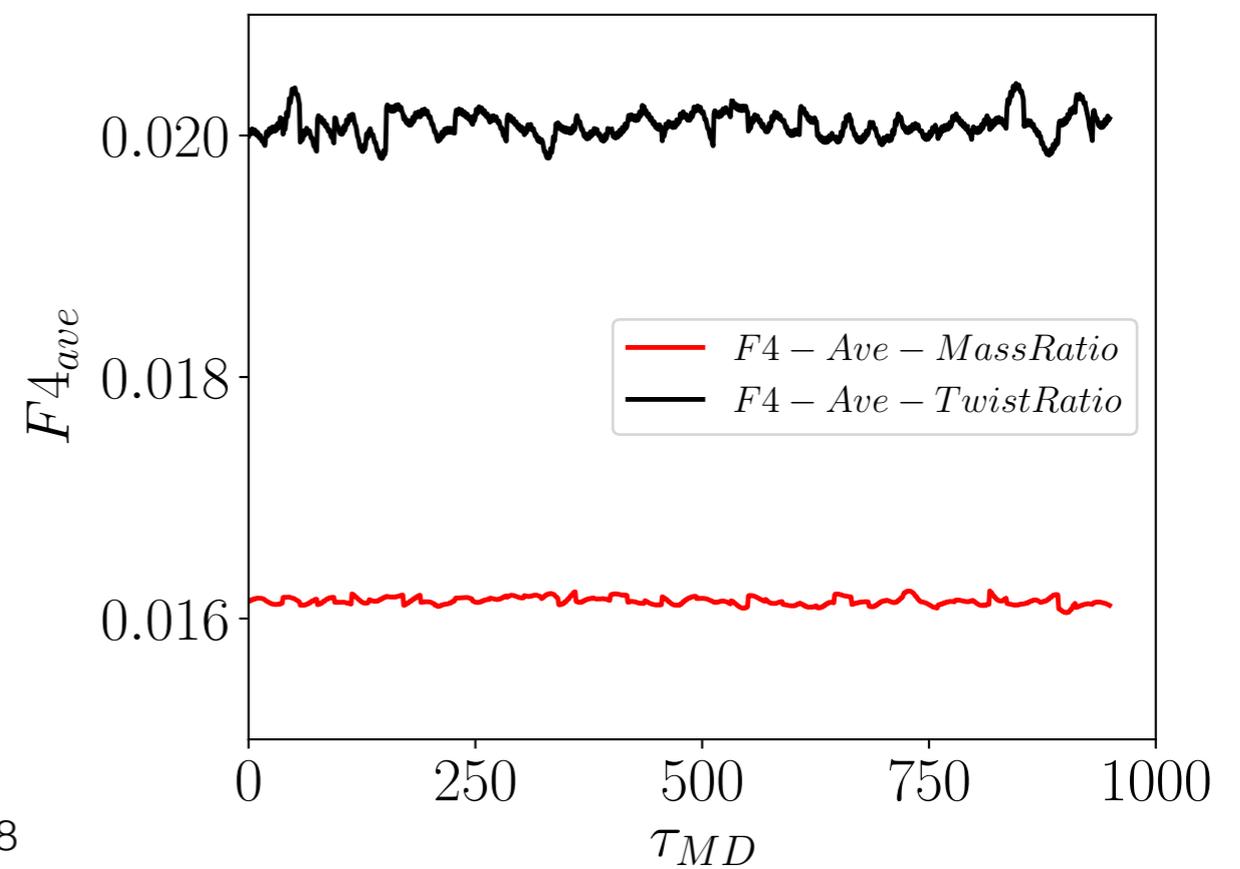

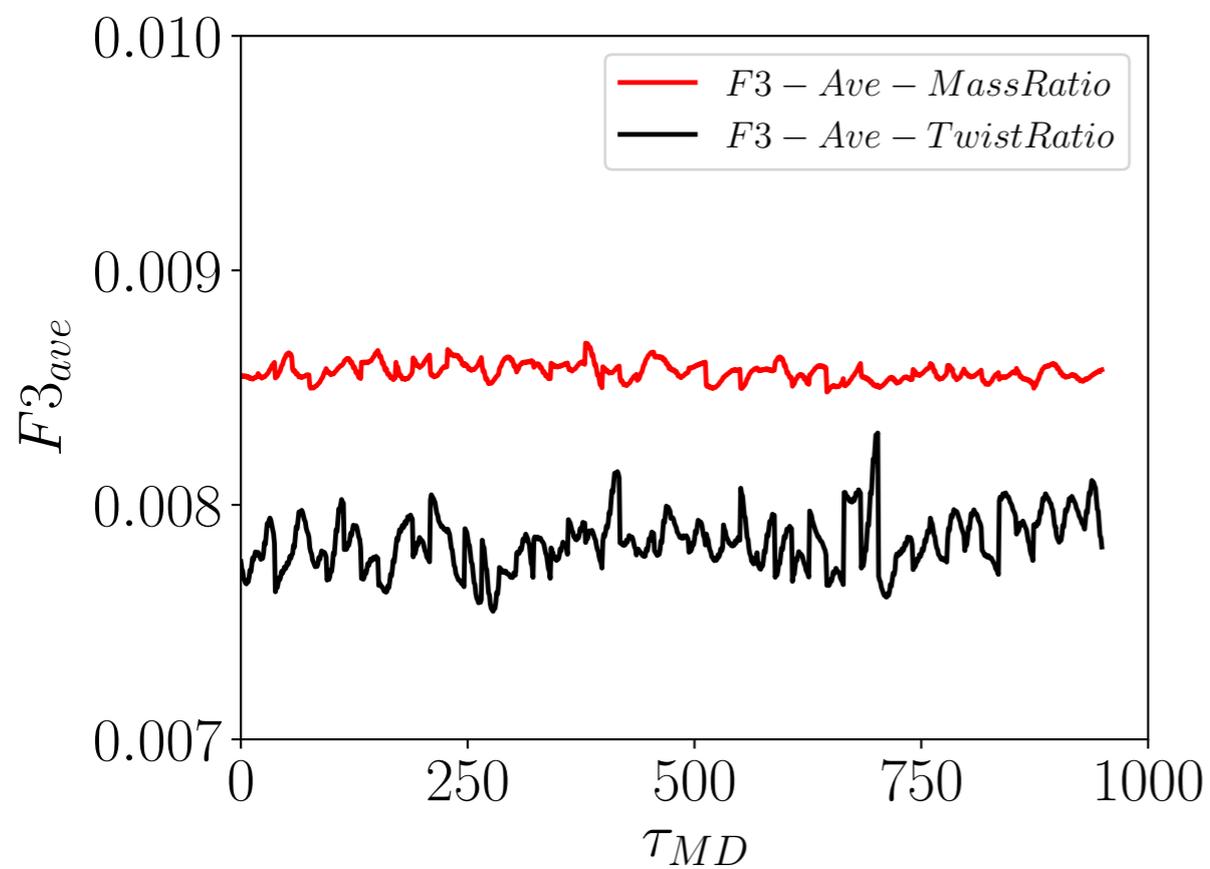

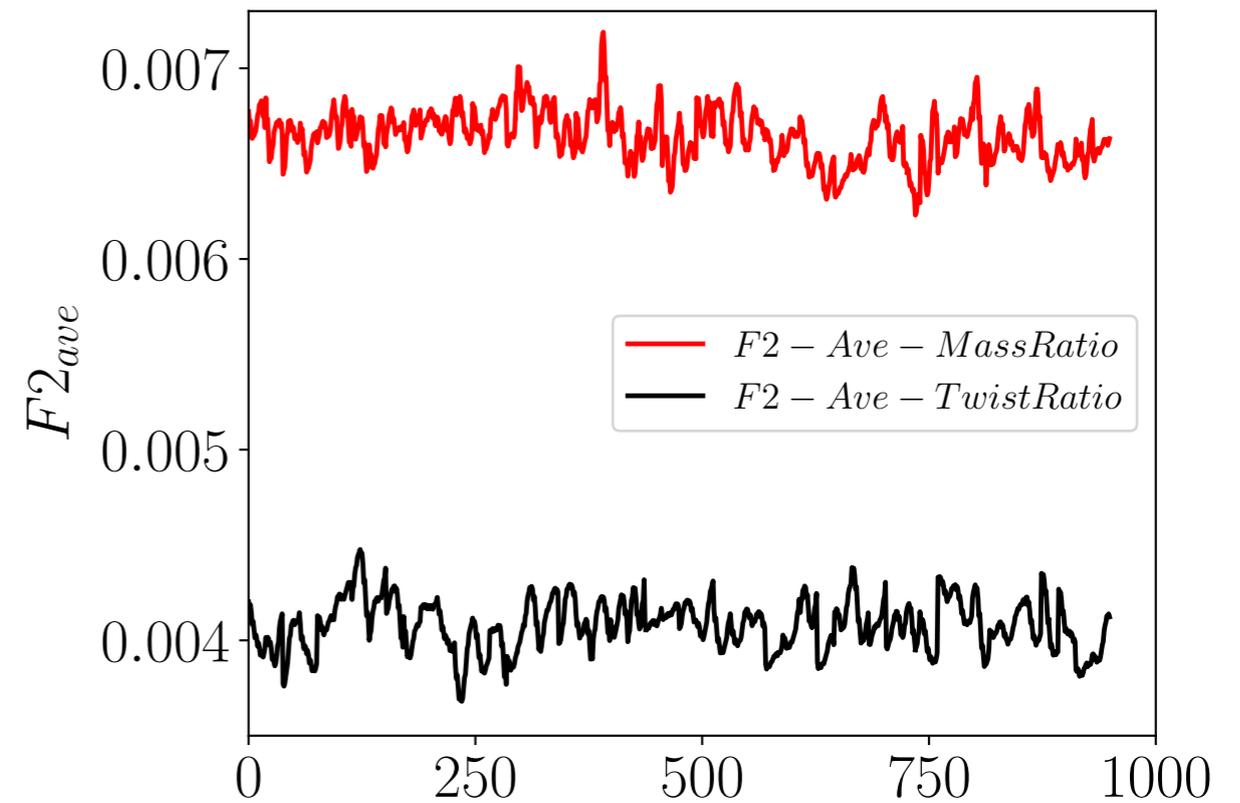

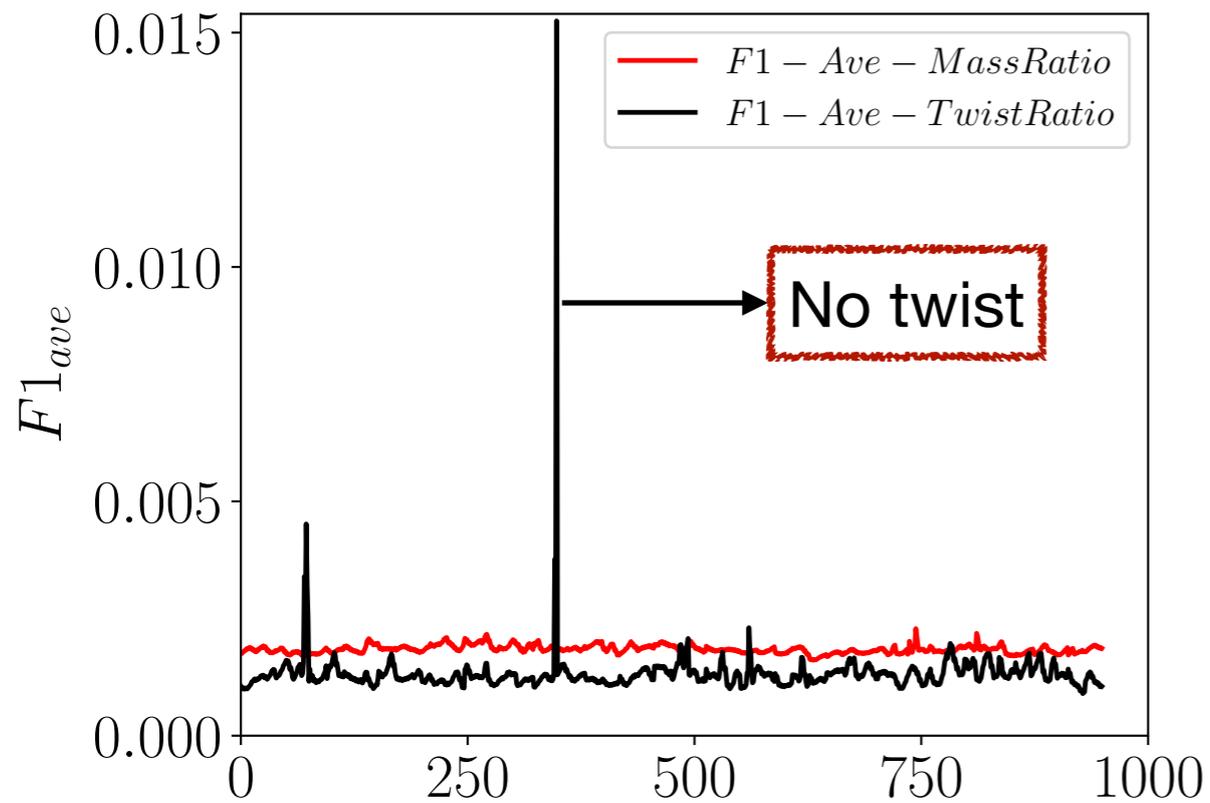

$F4$

$Fcancel$

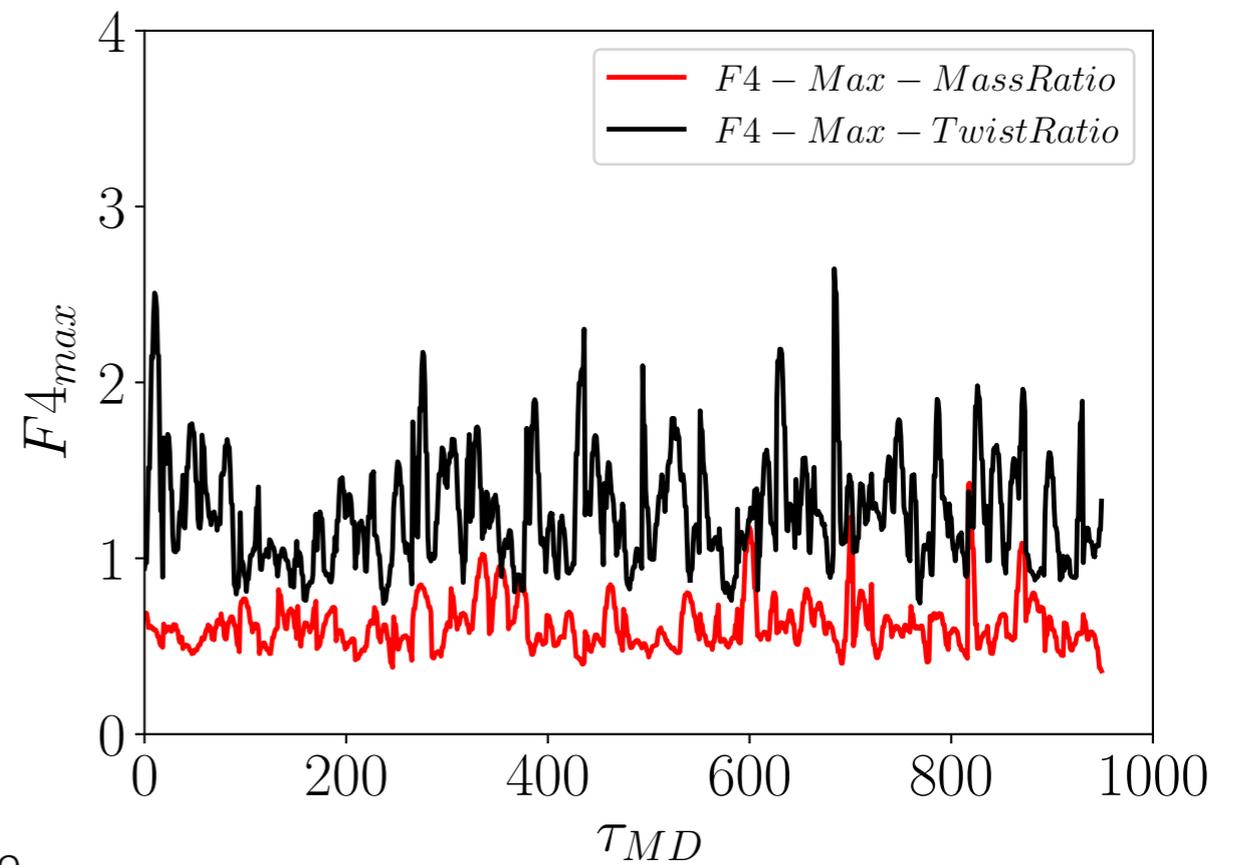

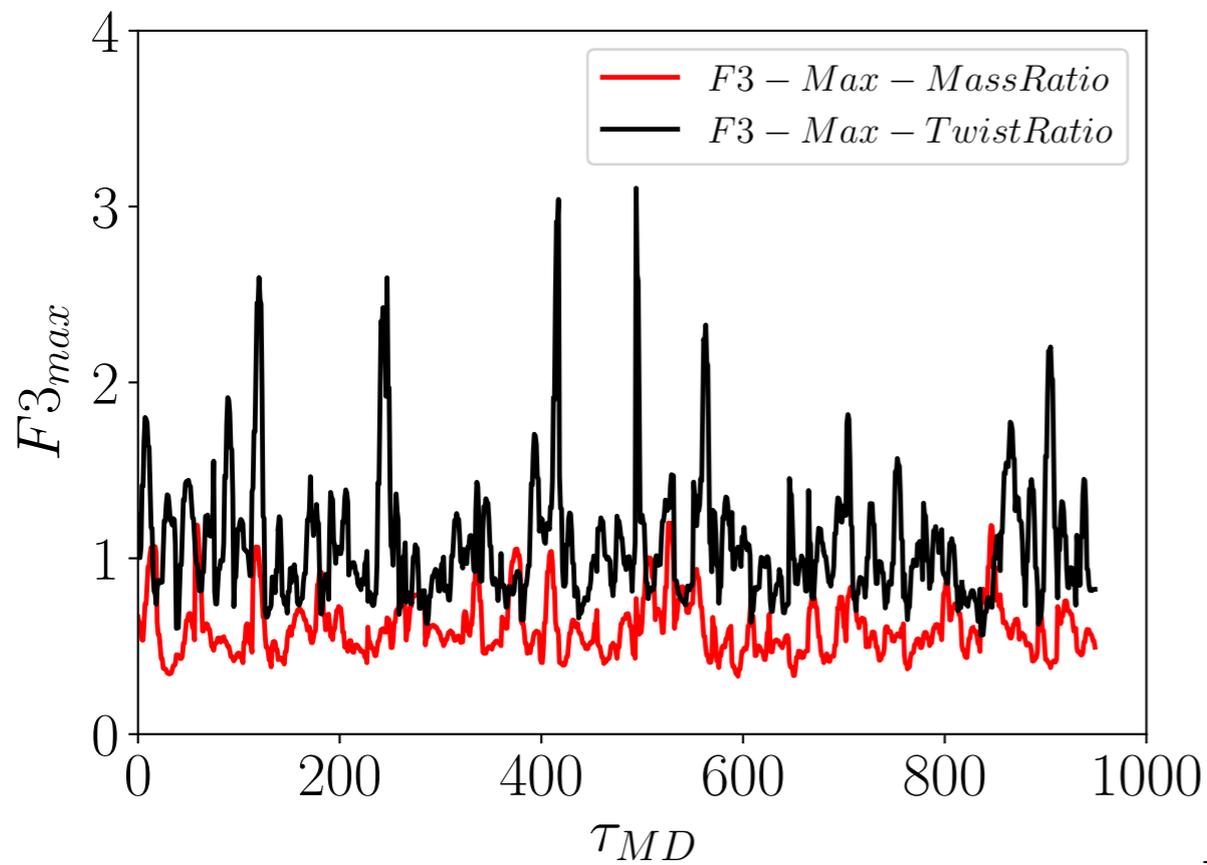

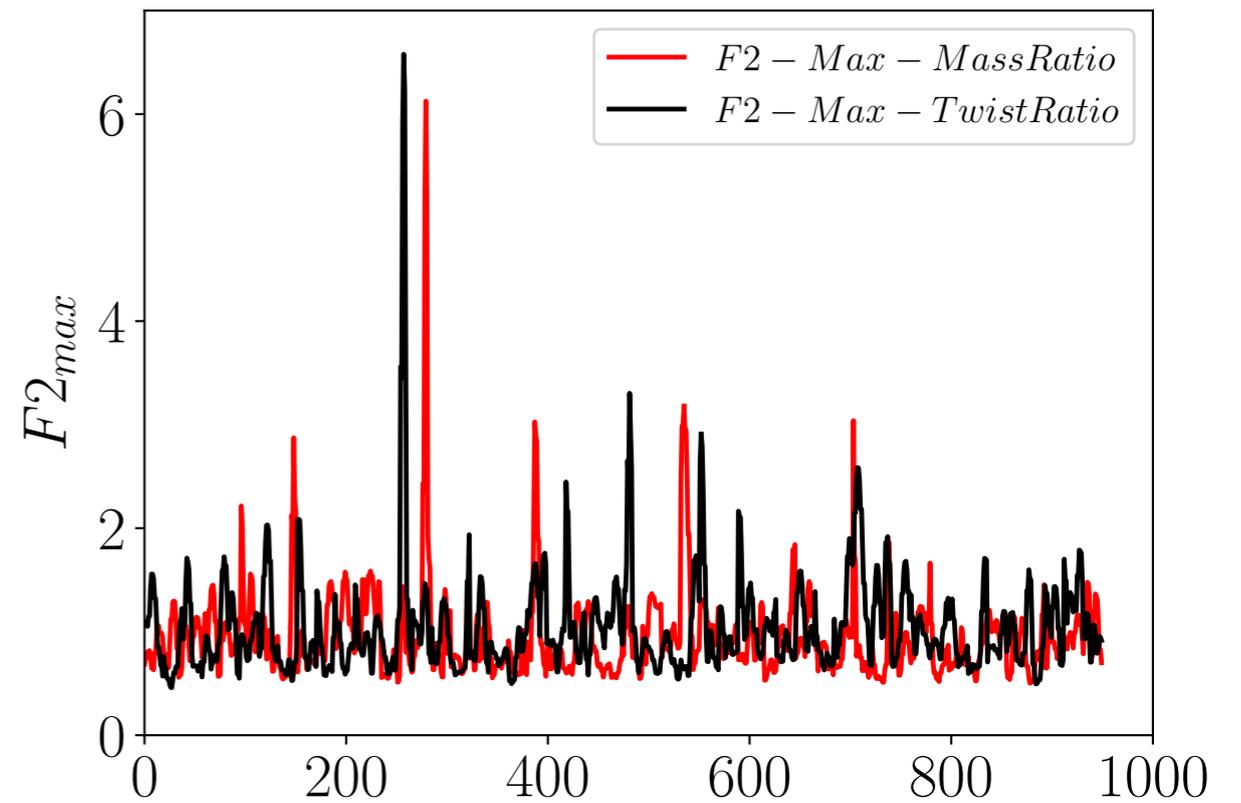

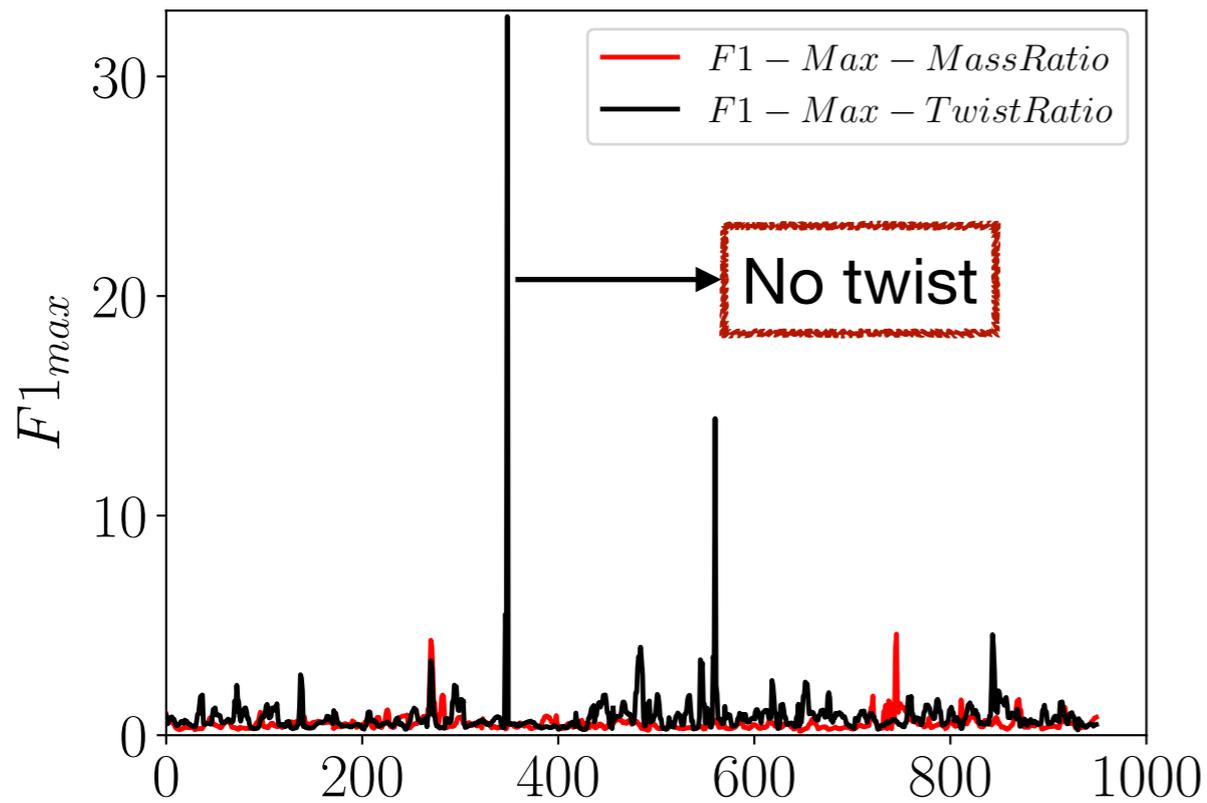

- Twist-Ratio parameter:

$$\triangleright \frac{[0]}{[0.00035]} \times \frac{[0.00035]}{[0.0015]} \times \frac{[0.0015]}{[0.005]} \times \frac{[0.005]}{[0.0175]} \times [0.0175]$$

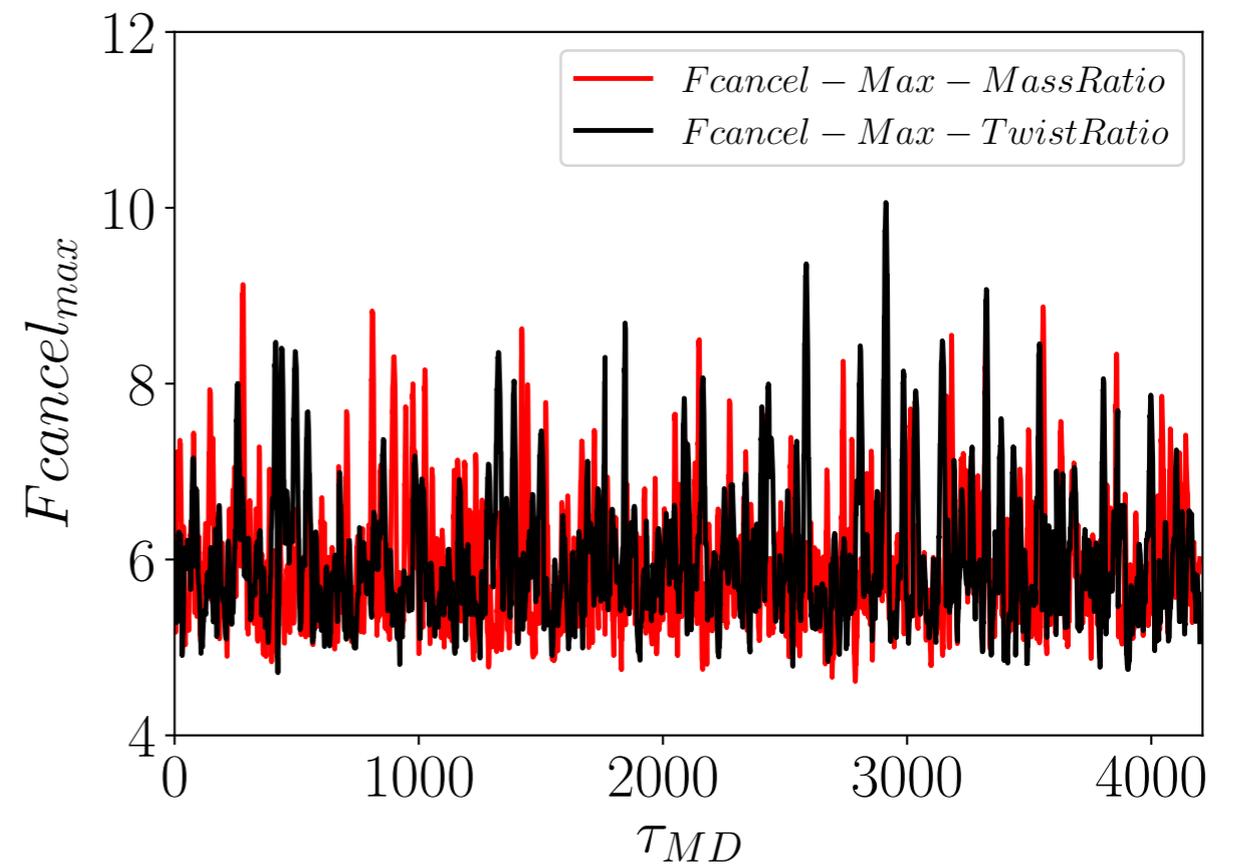

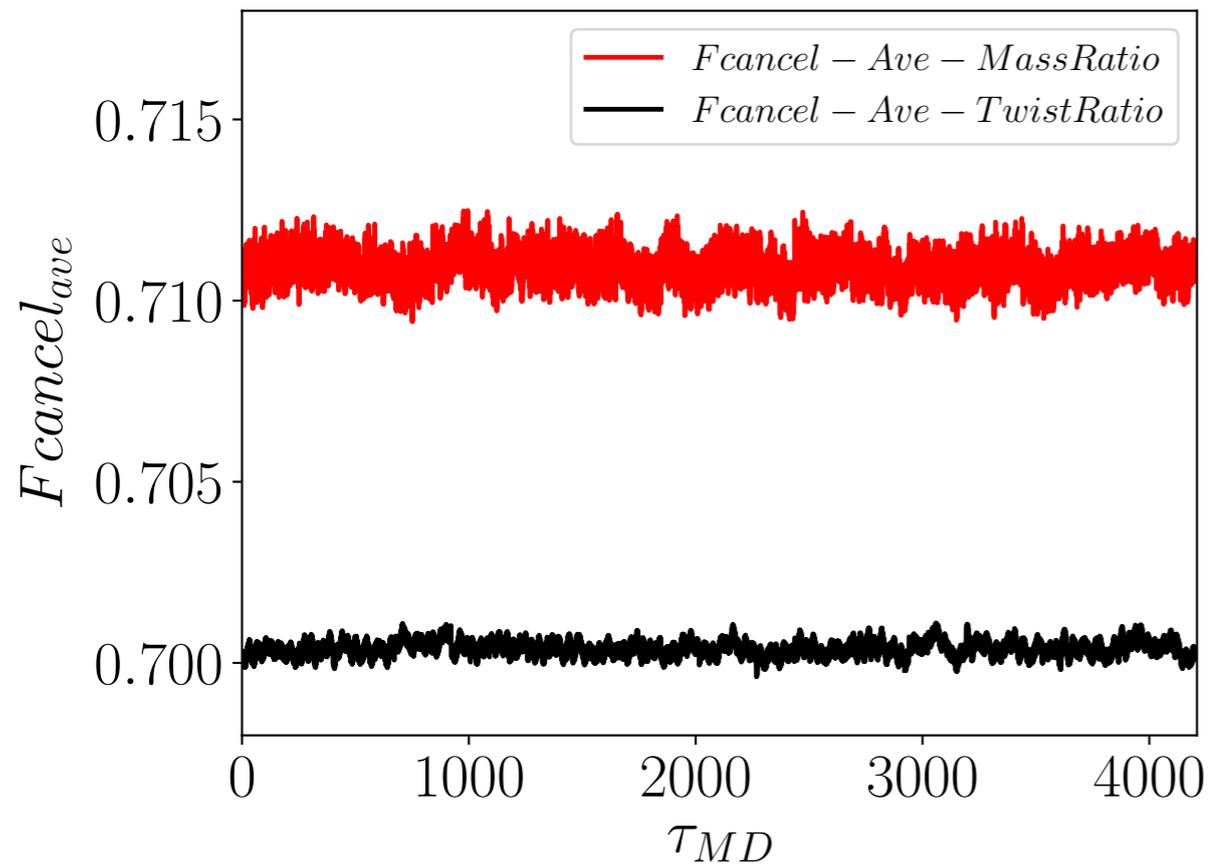

Average Fermionic Force – Ratio Term F_{ave}

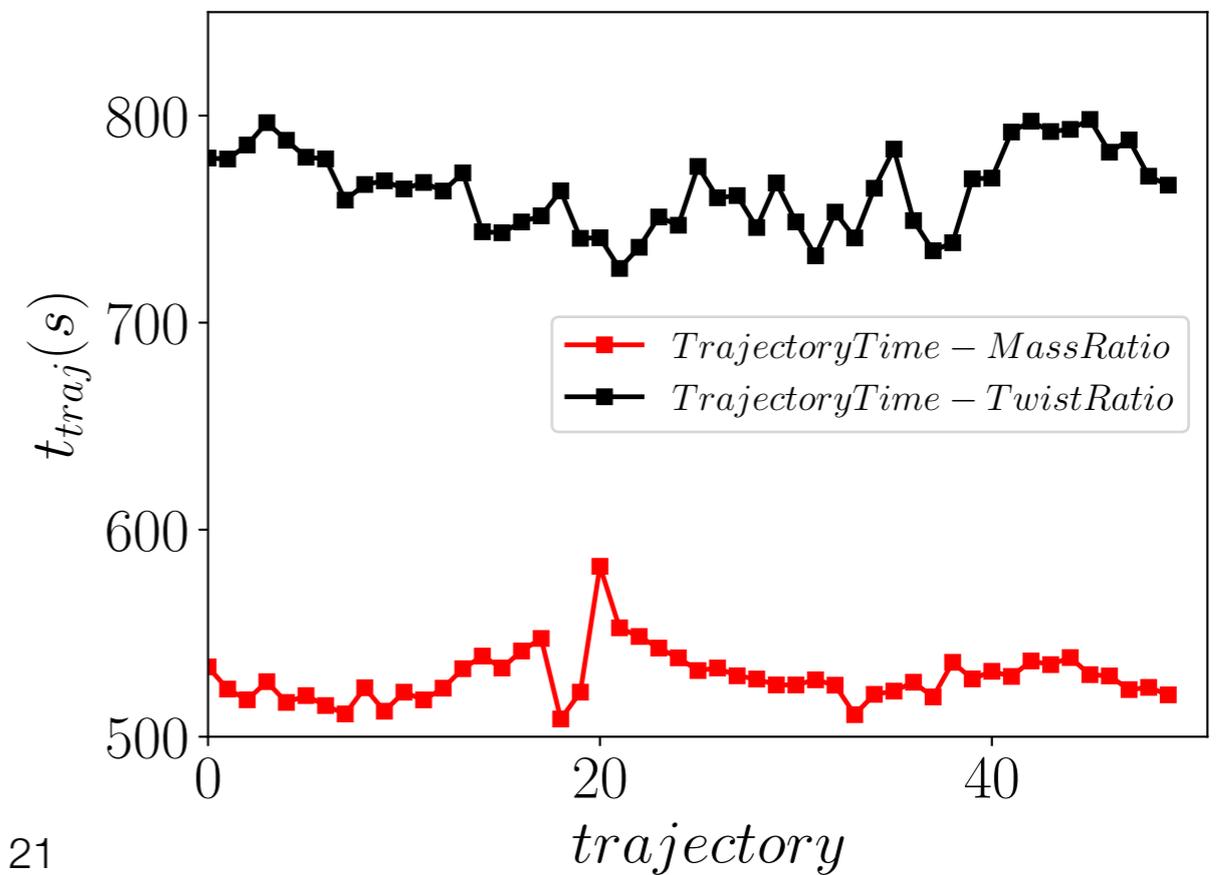

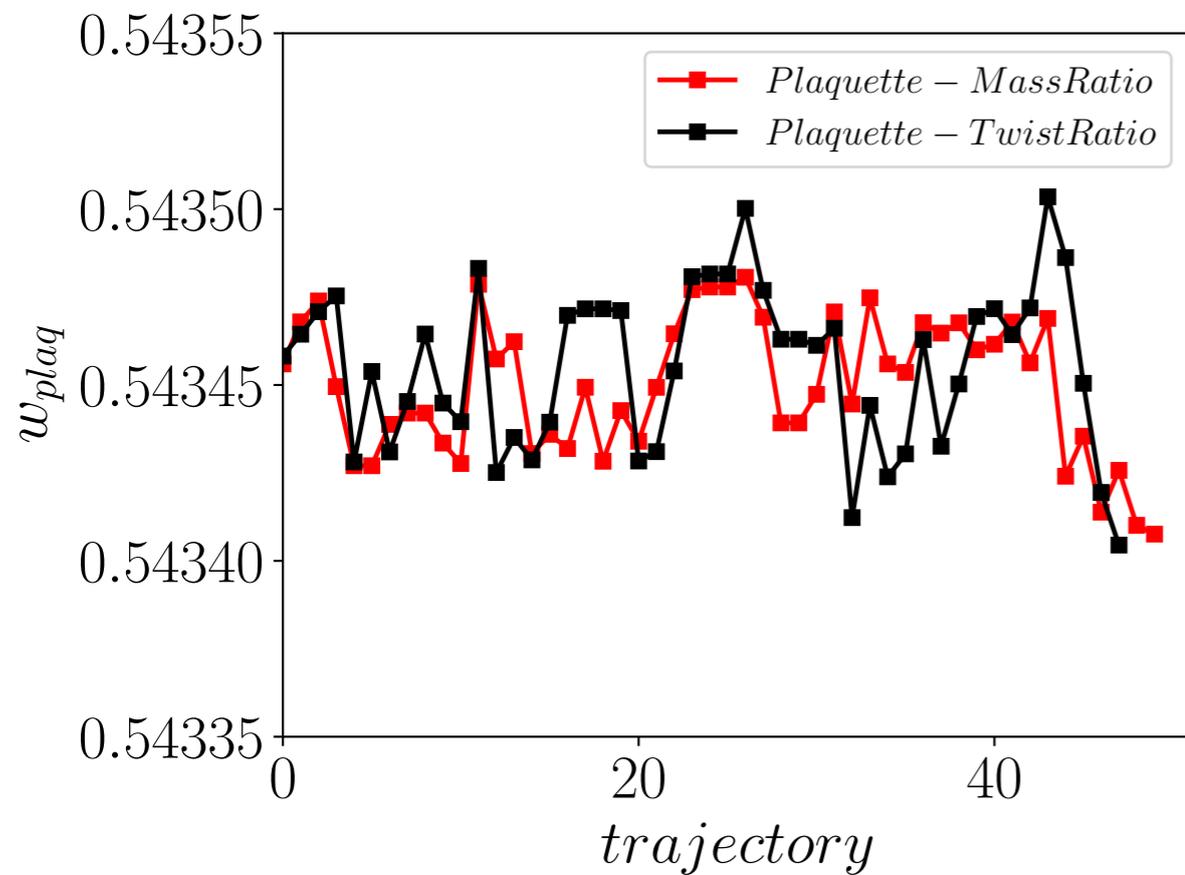

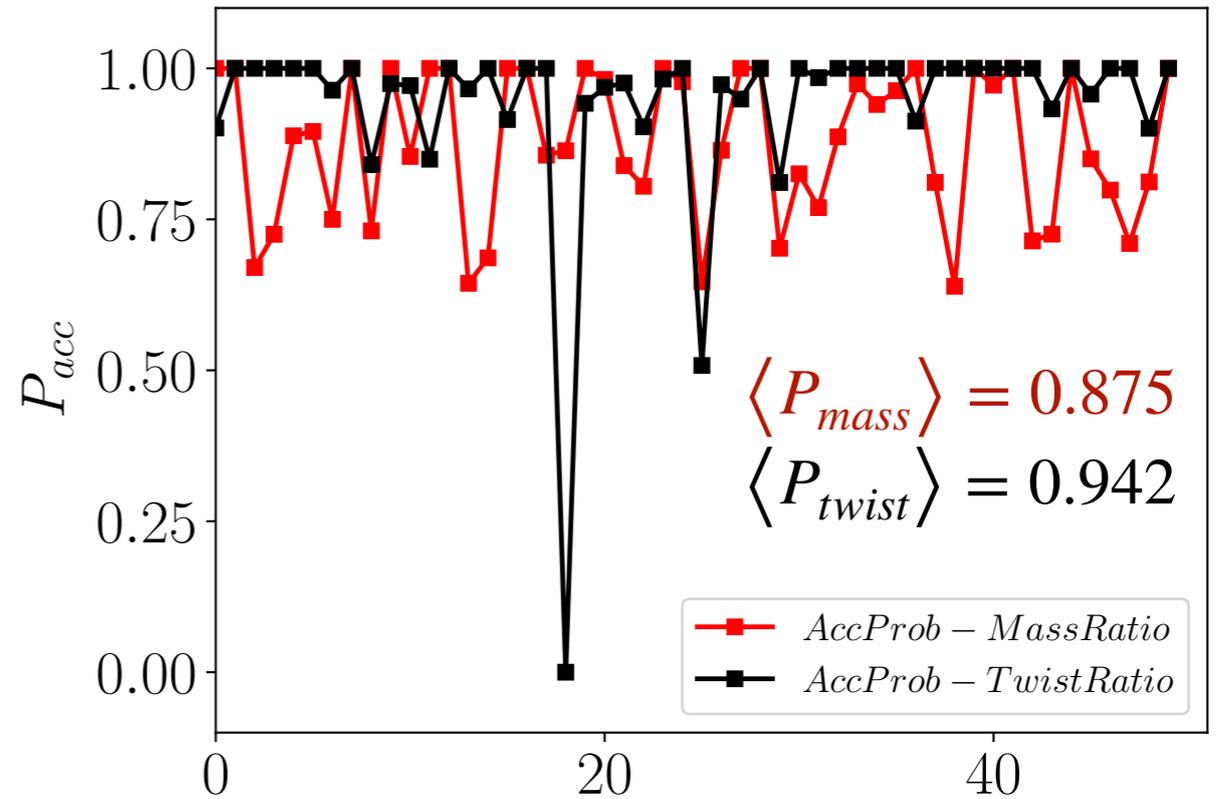

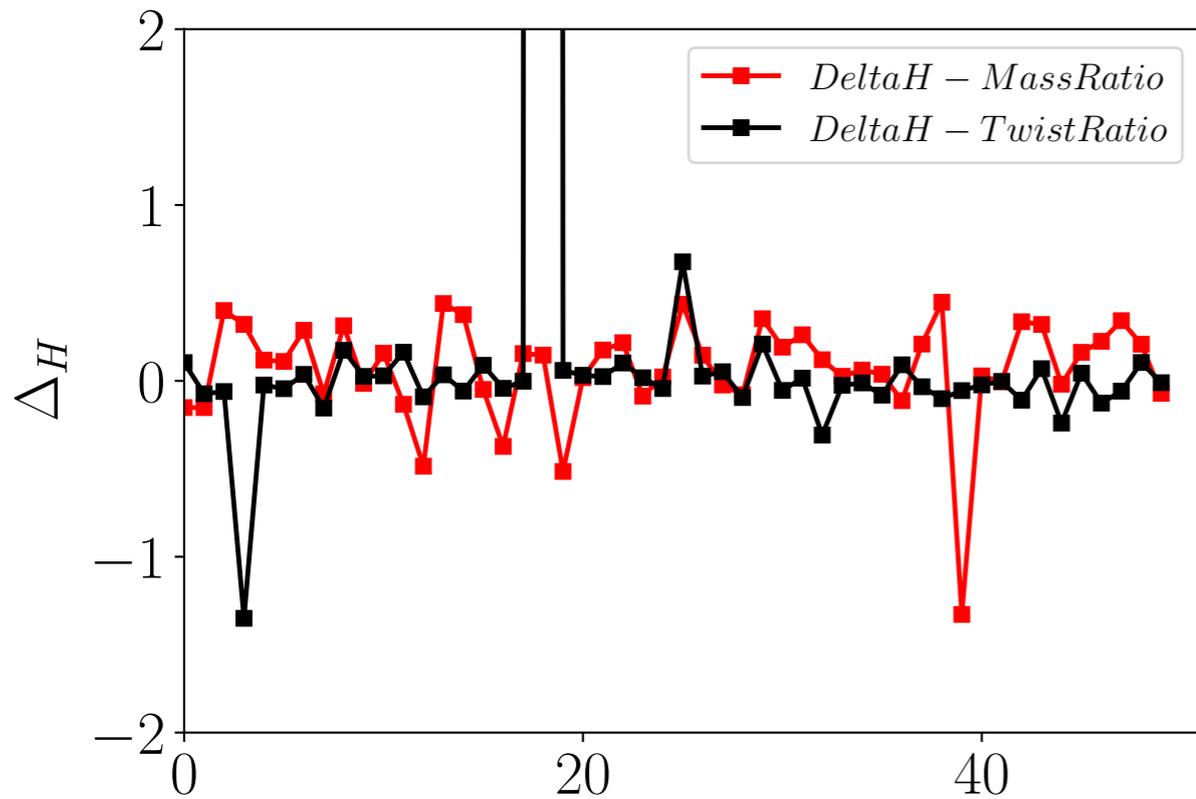

Maximum Fermionic Force – Ratio Term F_{max}

Fermionic Force — Cancel Term F_{cancel}

MD Integration Stability

Problems & Improvement

- No twist μ for the first ratio term ($F1$)
- Near zero mode \rightarrow large $F1 \rightarrow$ MD integration unstable
- Add a small twist to the first ratio term in **MD integration**

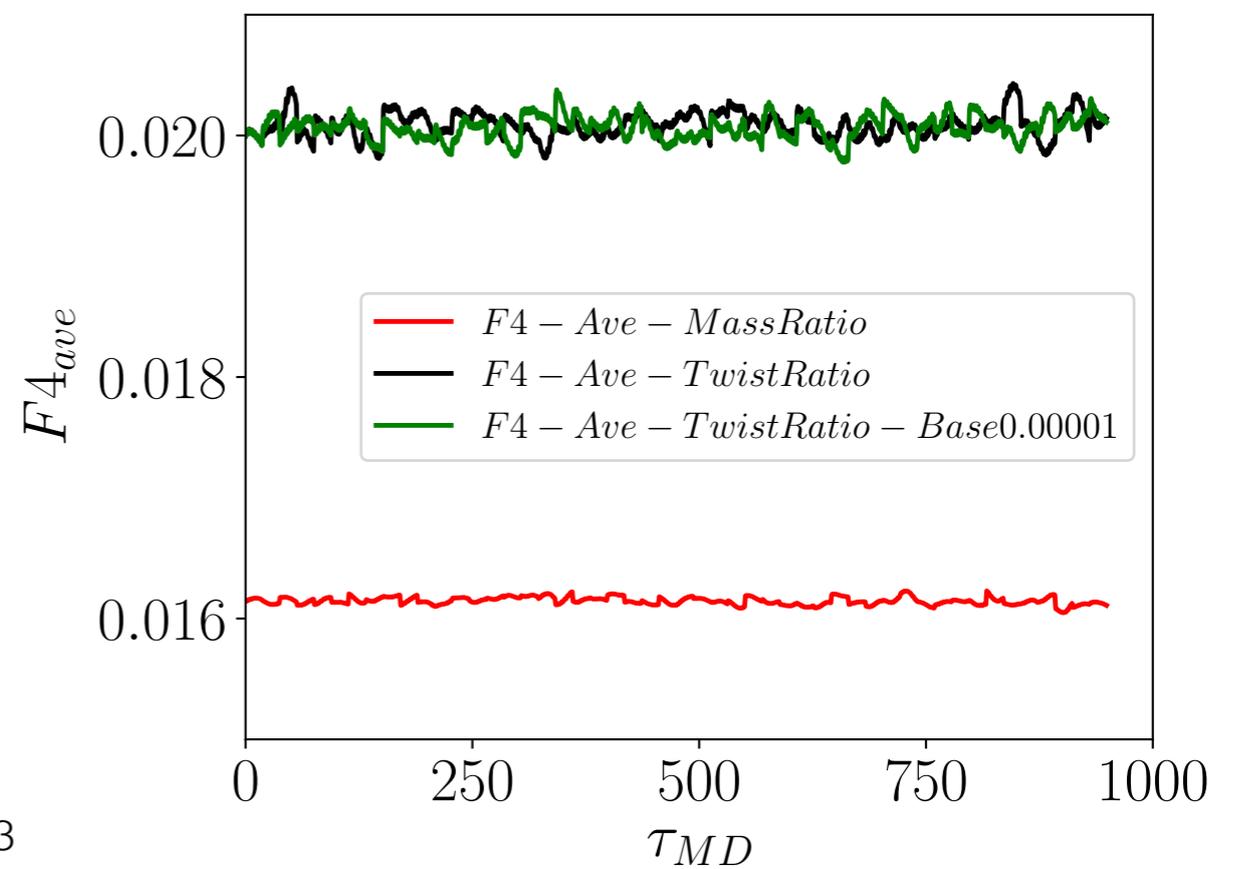

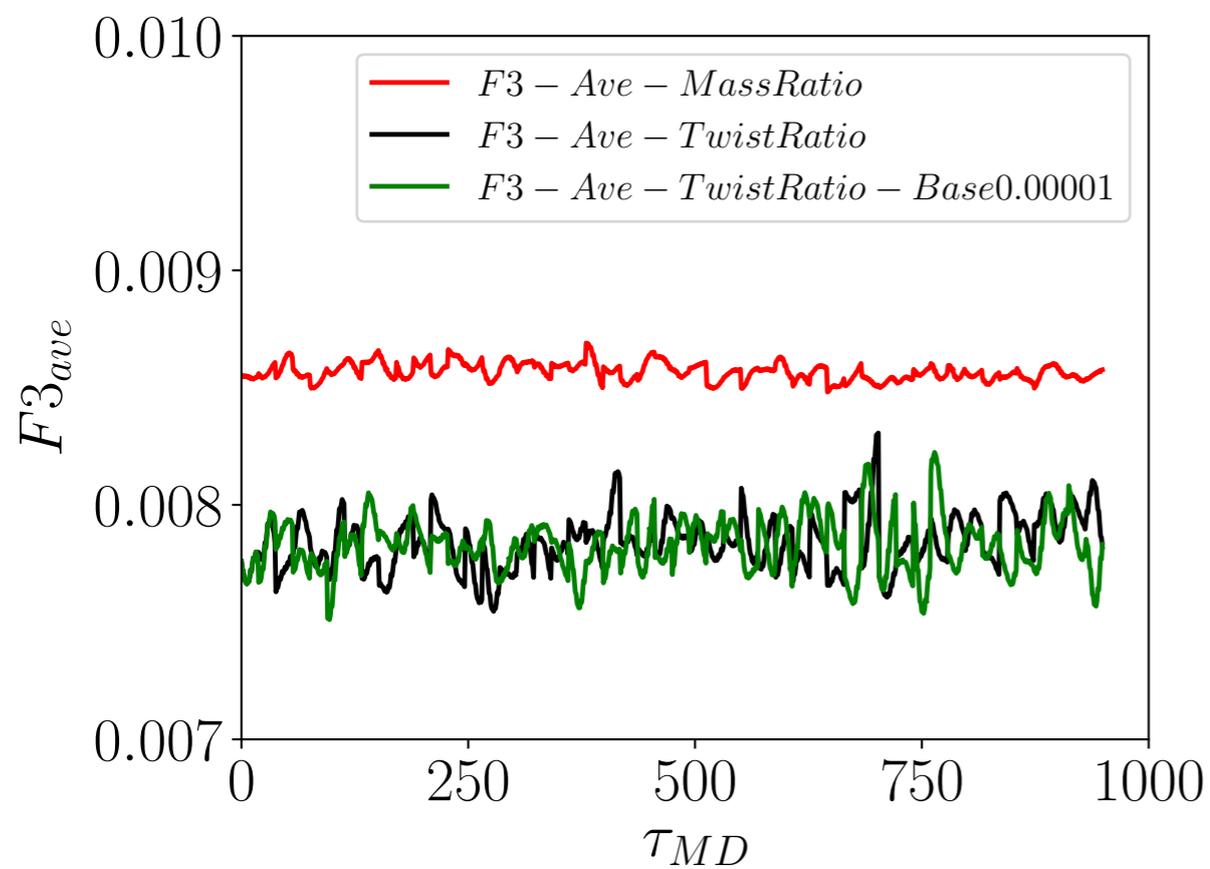

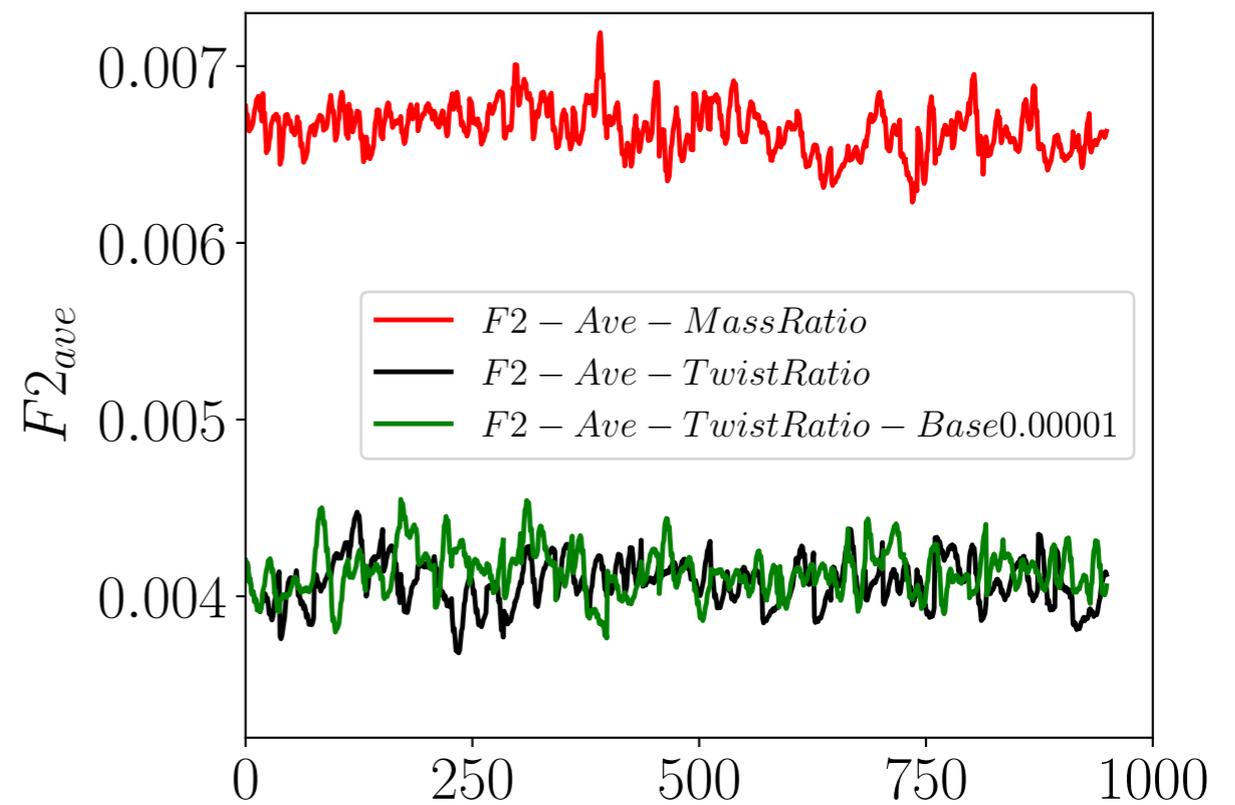

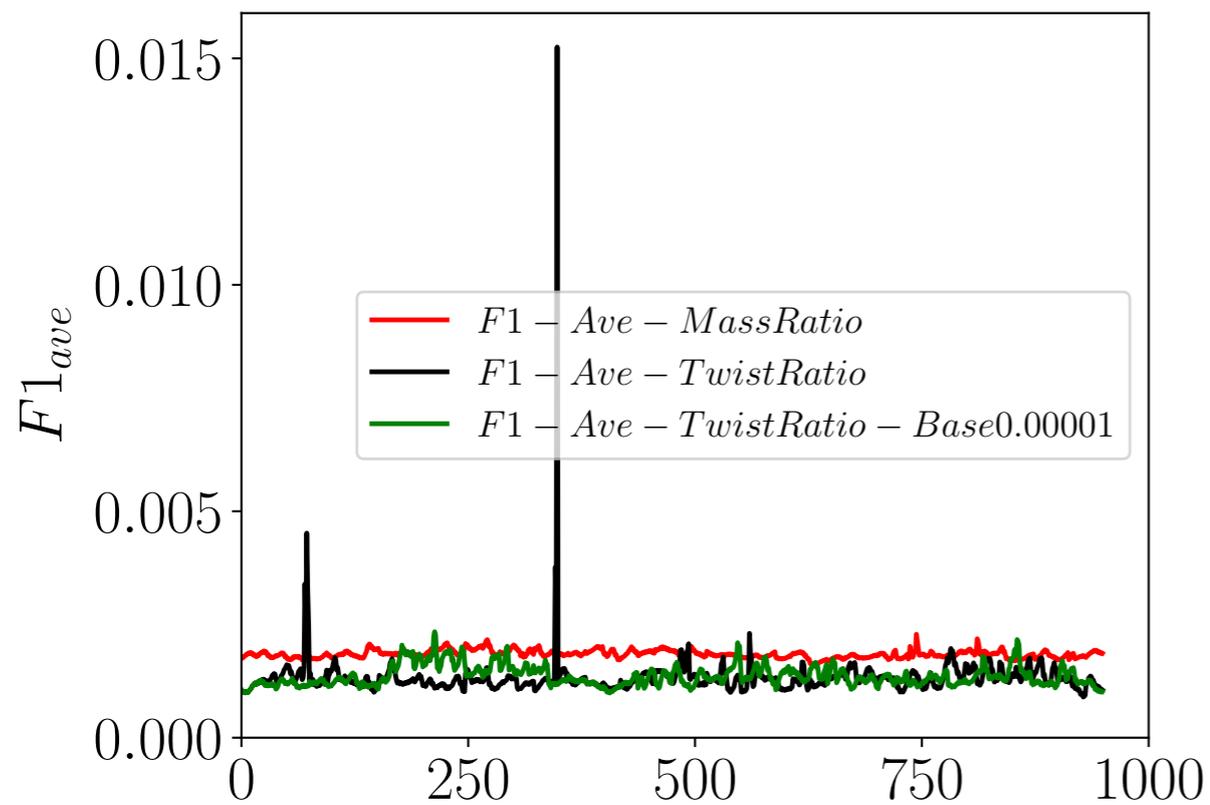

$$\triangleright \frac{[0]}{[0.00035]} \times \frac{[0.00035]}{[0.0015]} \times \frac{[0.0015]}{[0.005]} \times \frac{[0.005]}{[0.0175]} \times [0.0175]$$

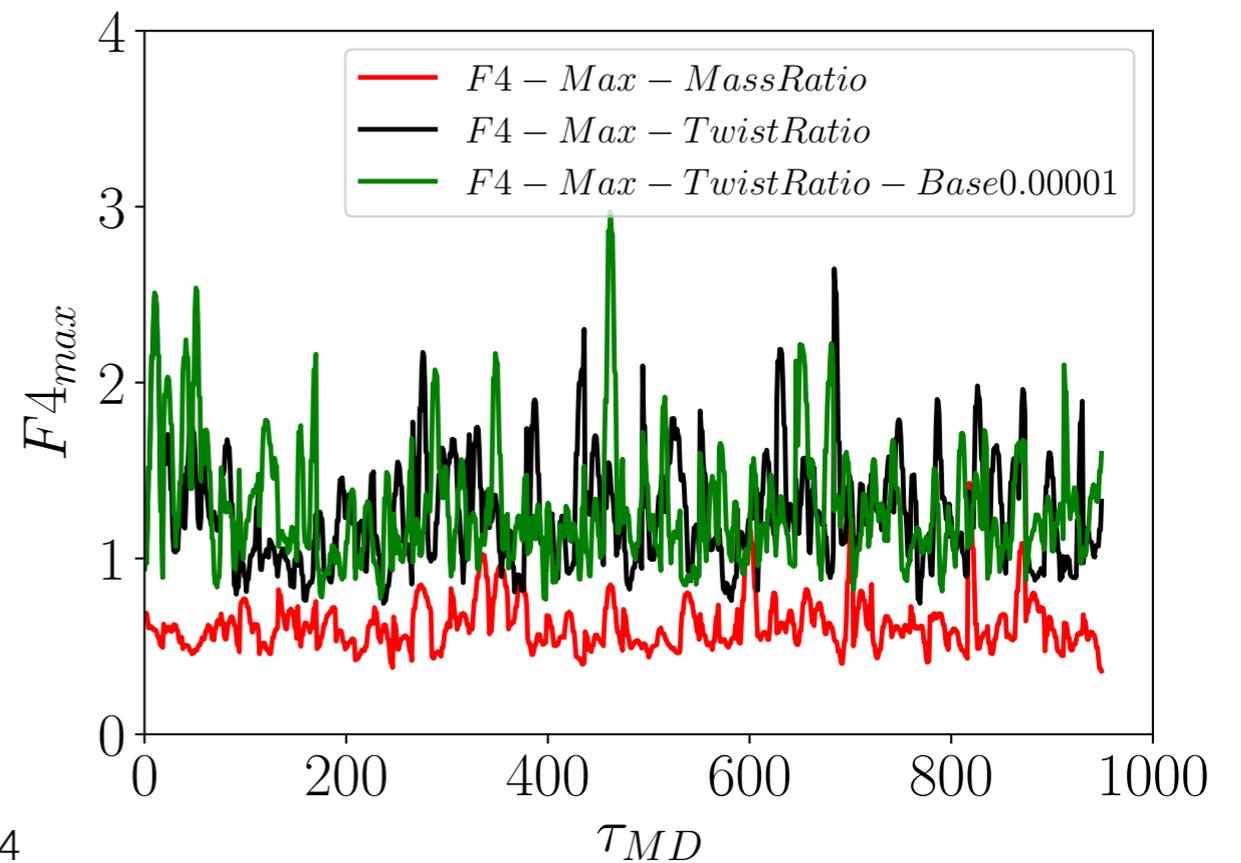

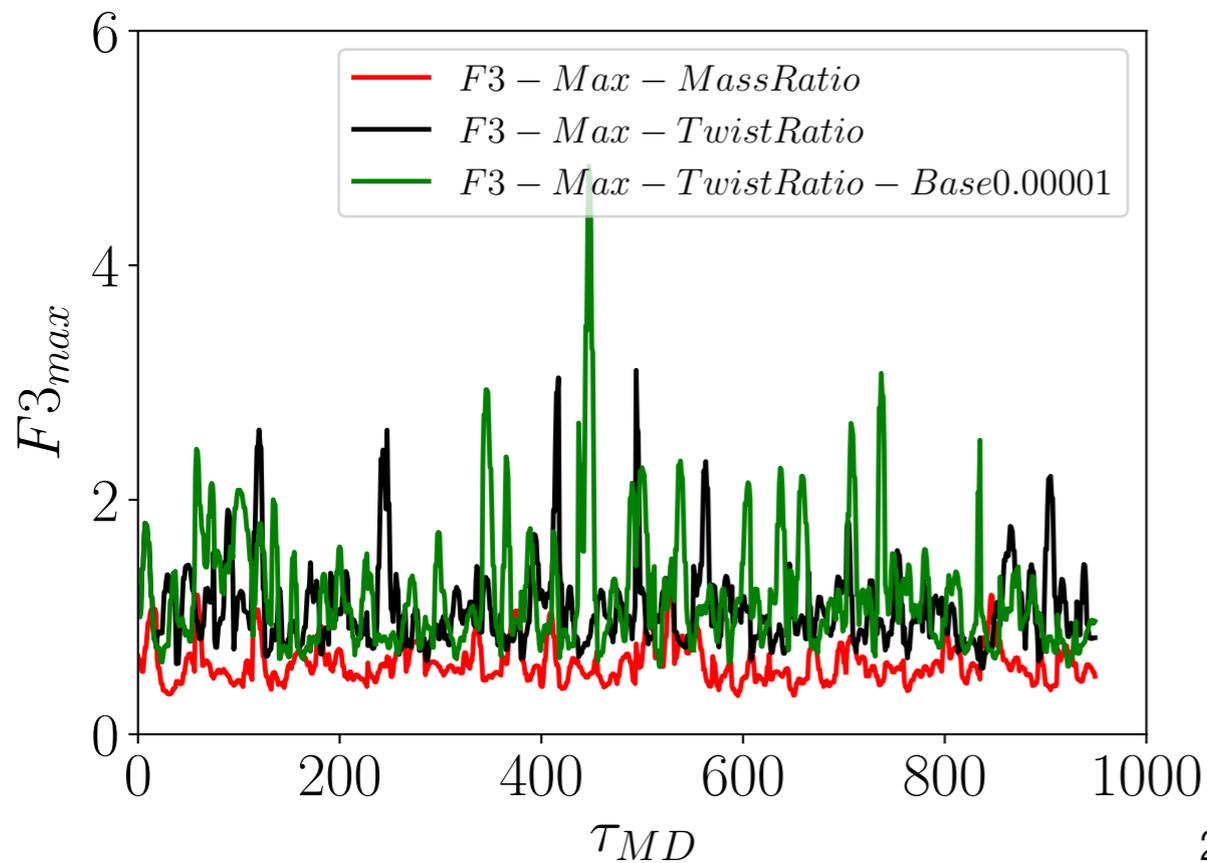

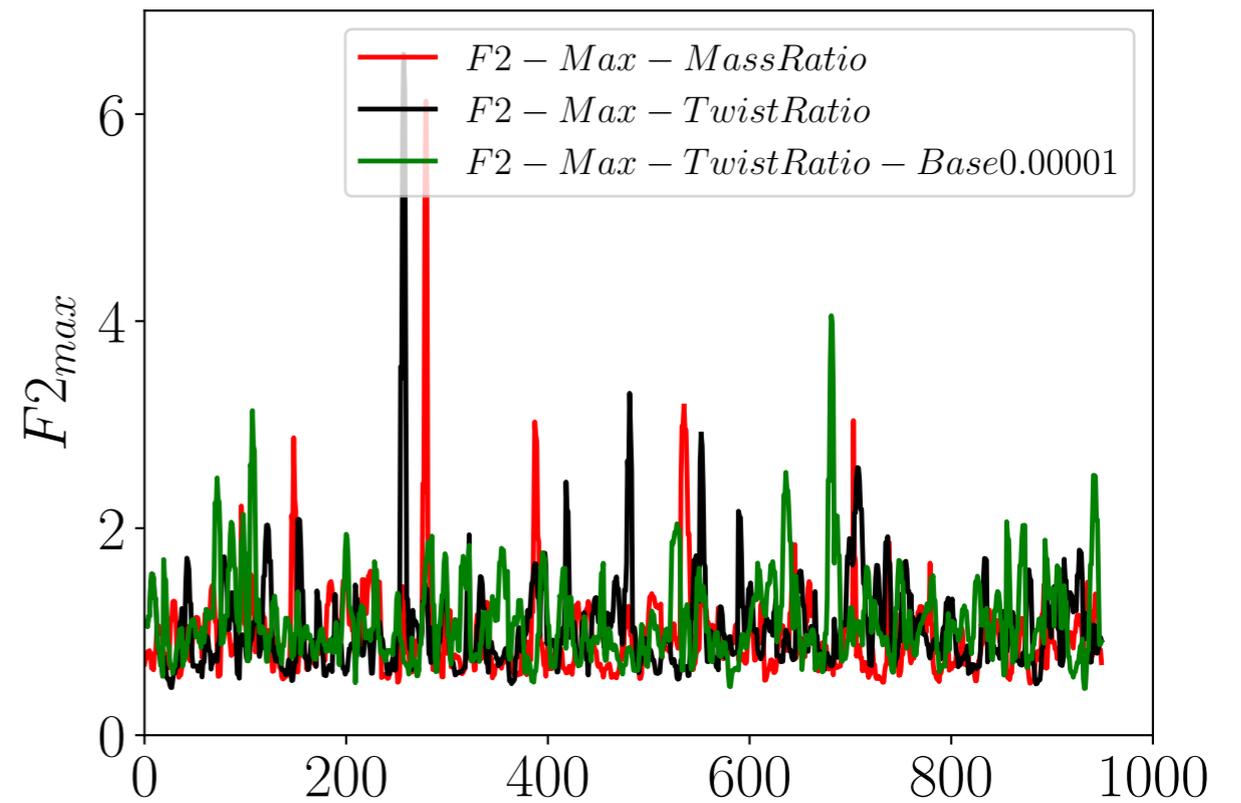

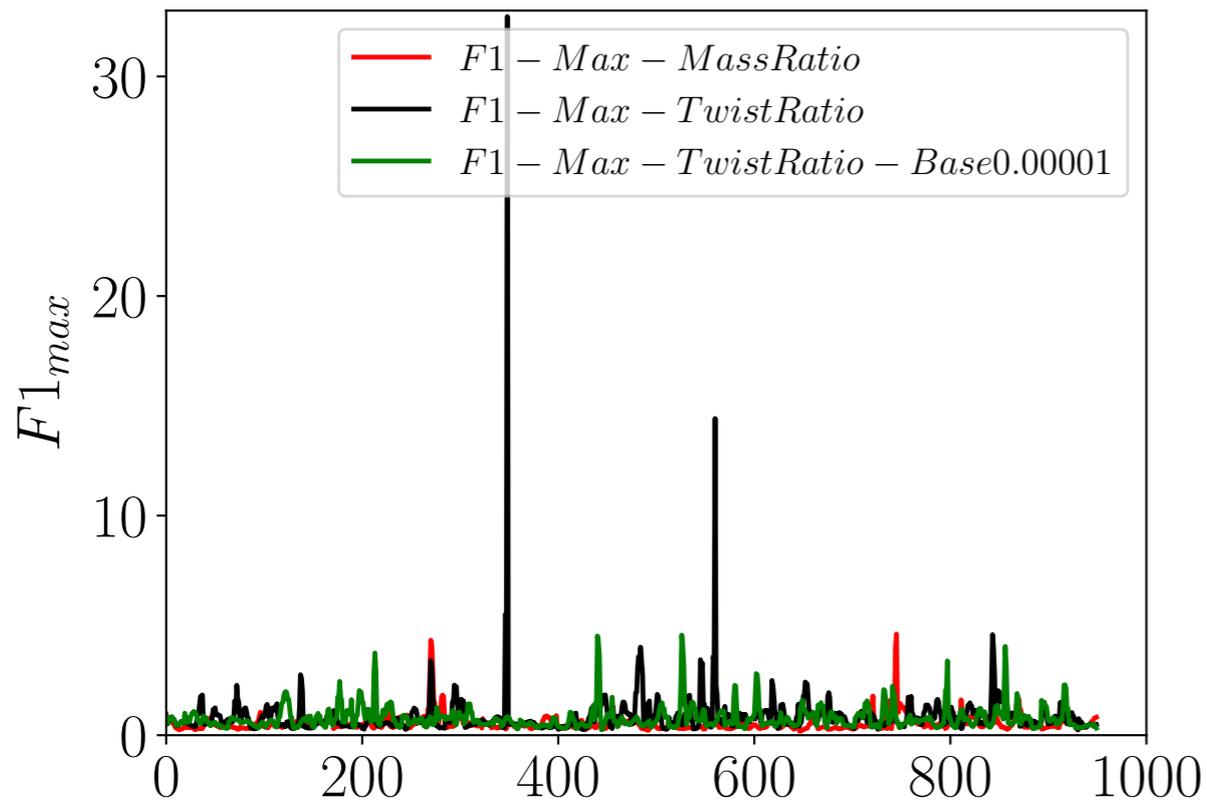

$$\triangleright \frac{[0.00001]}{[0.00035]} \times \frac{[0.00035]}{[0.0015]} \times \frac{[0.0015]}{[0.005]} \times \frac{[0.005]}{[0.0175]} \times [0.0175]$$

- No twist ($\mu = 0$) in the Accept/Reject (energy calculation)
- No twist in Dirac operator in **action** \rightarrow correct distribution

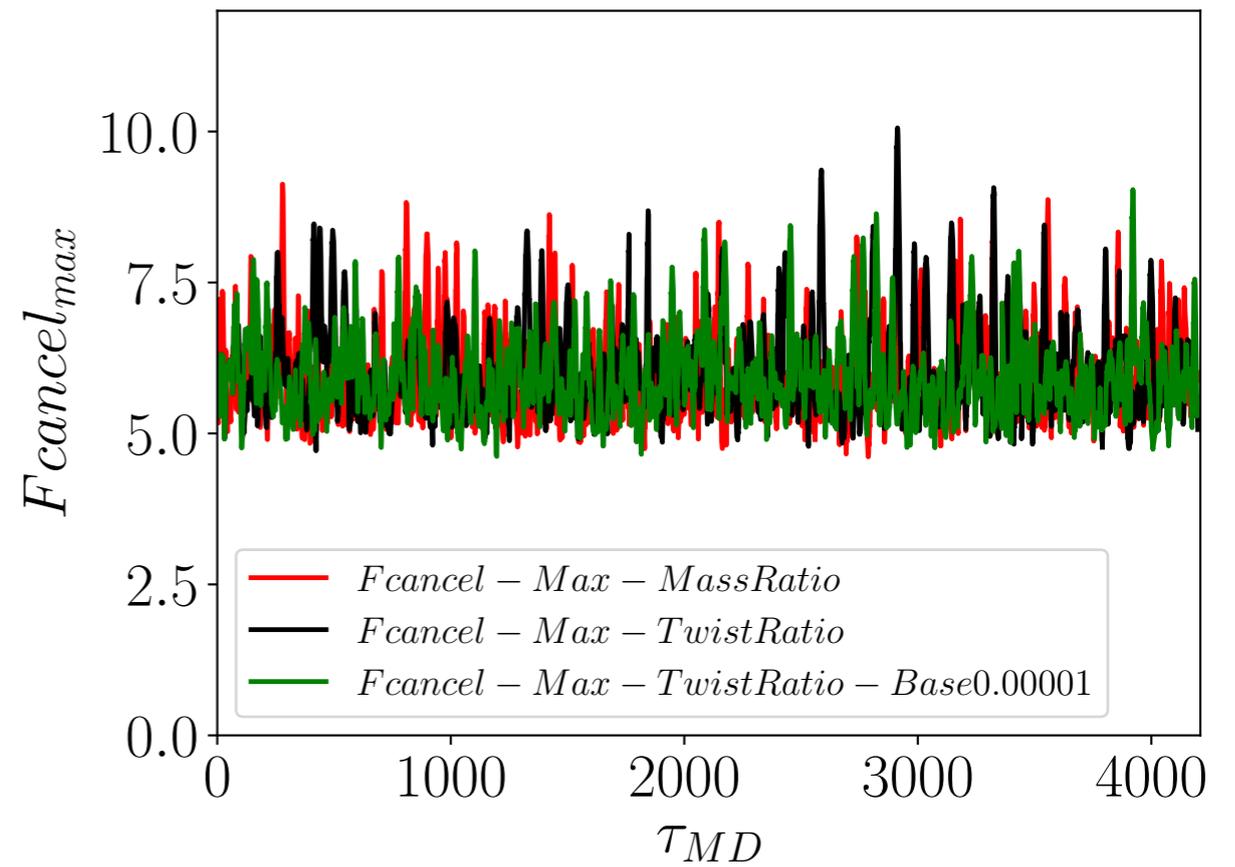

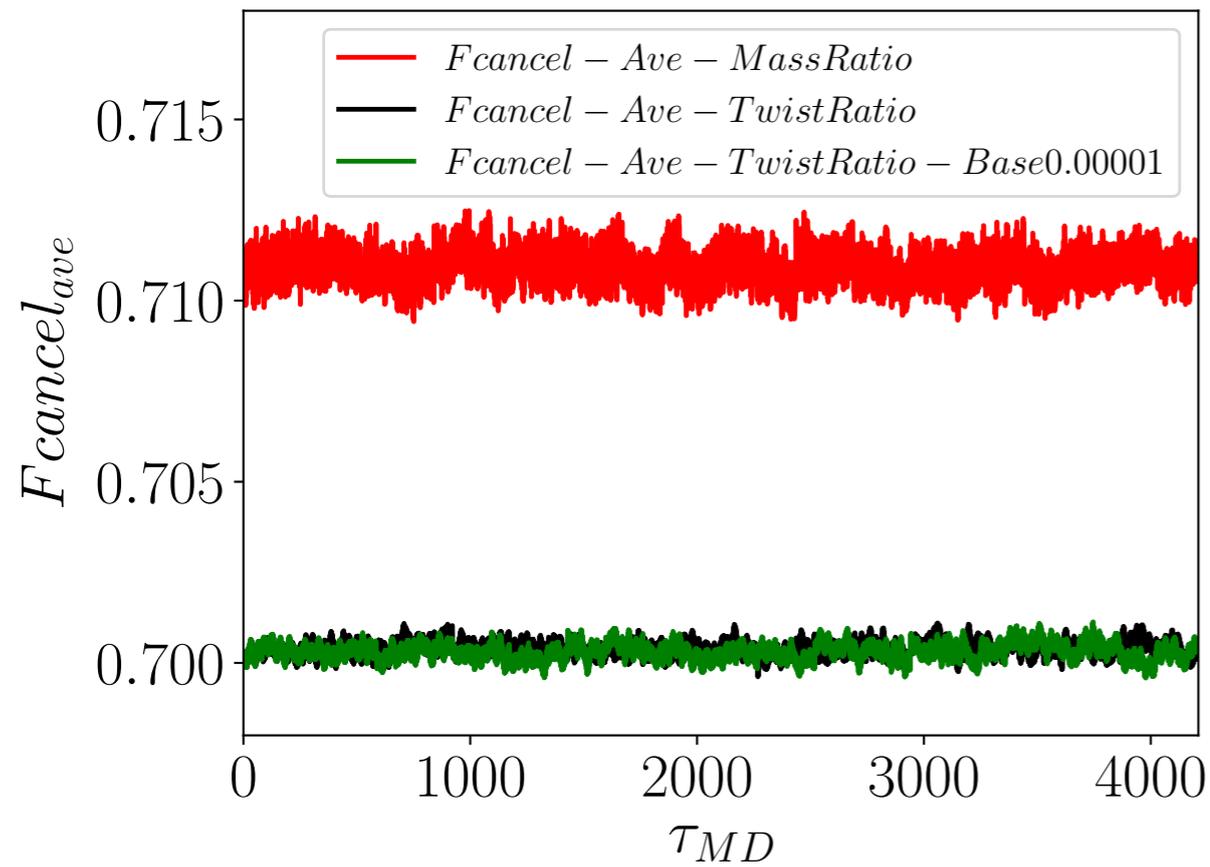

Average Fermionic Force – Ratio Term F_{ave}

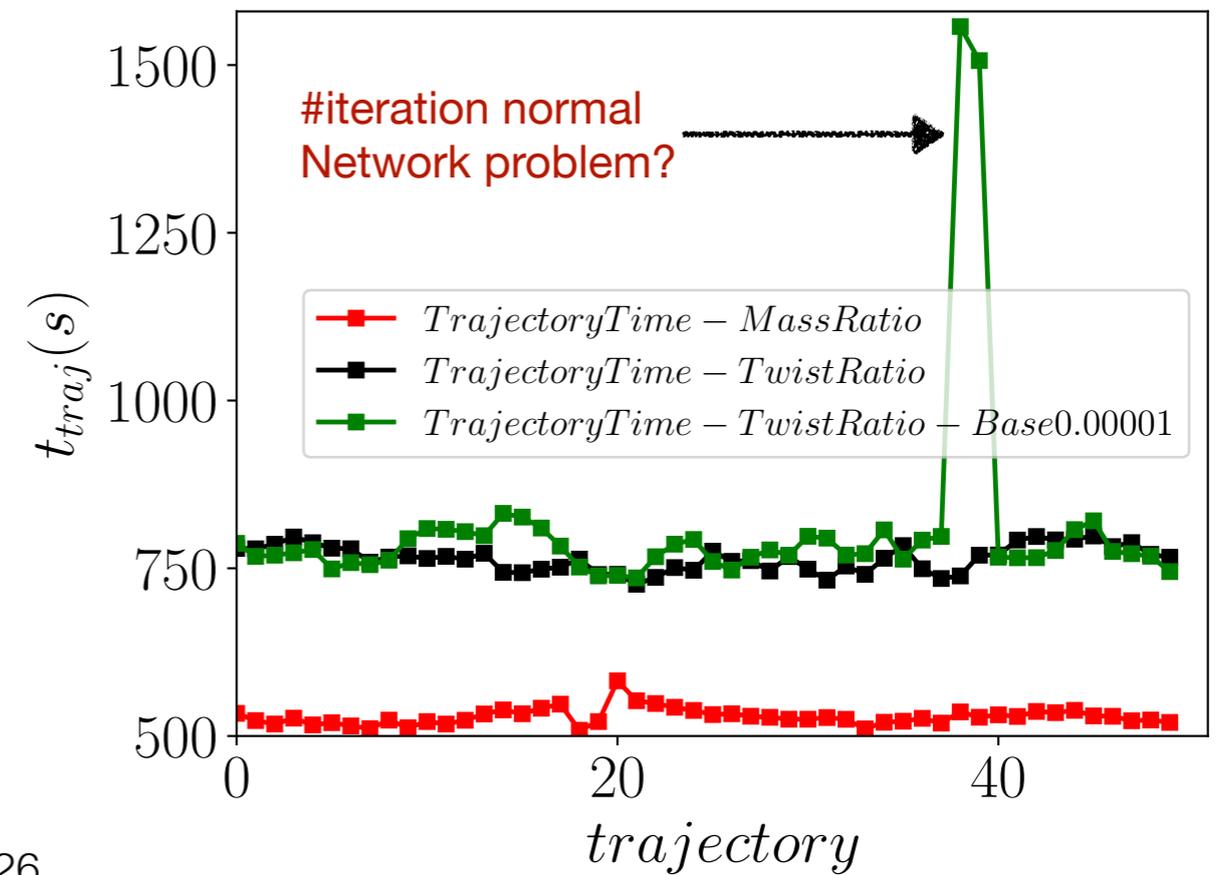

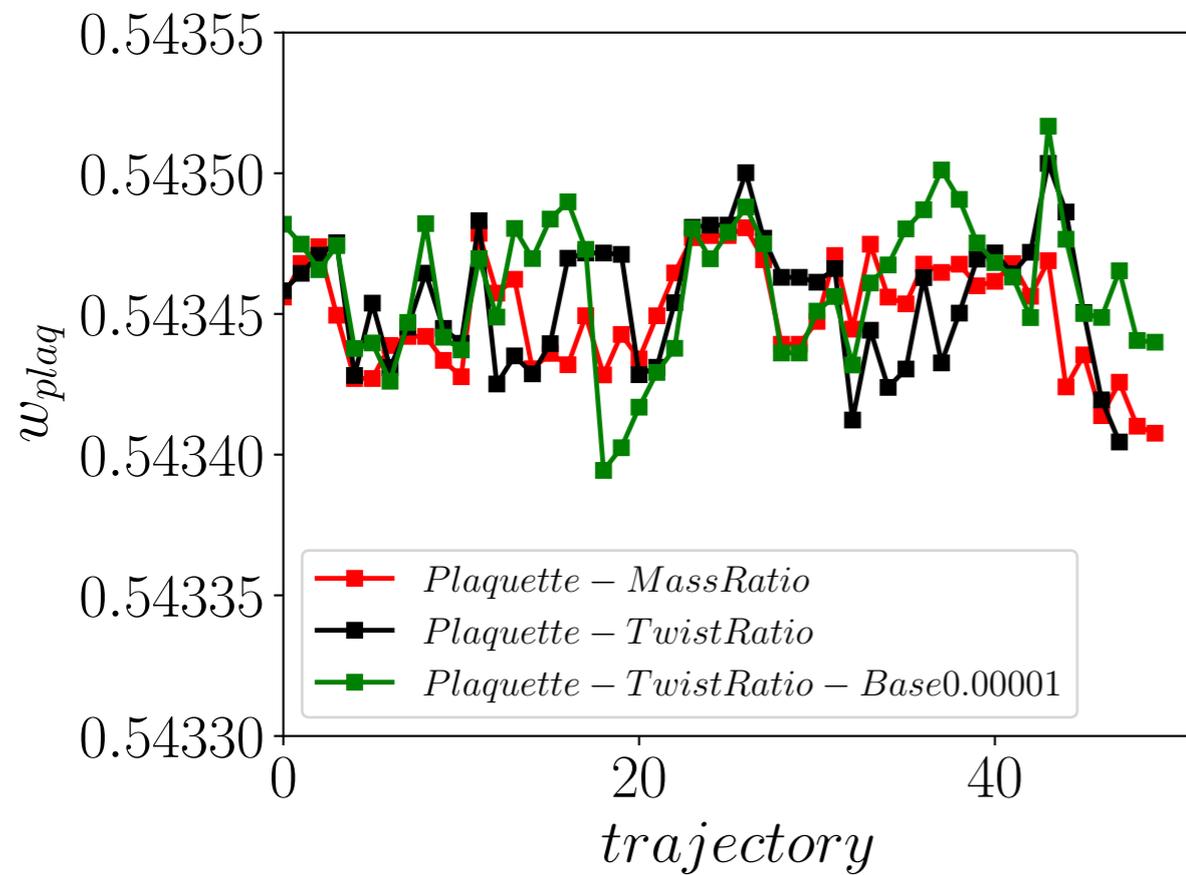

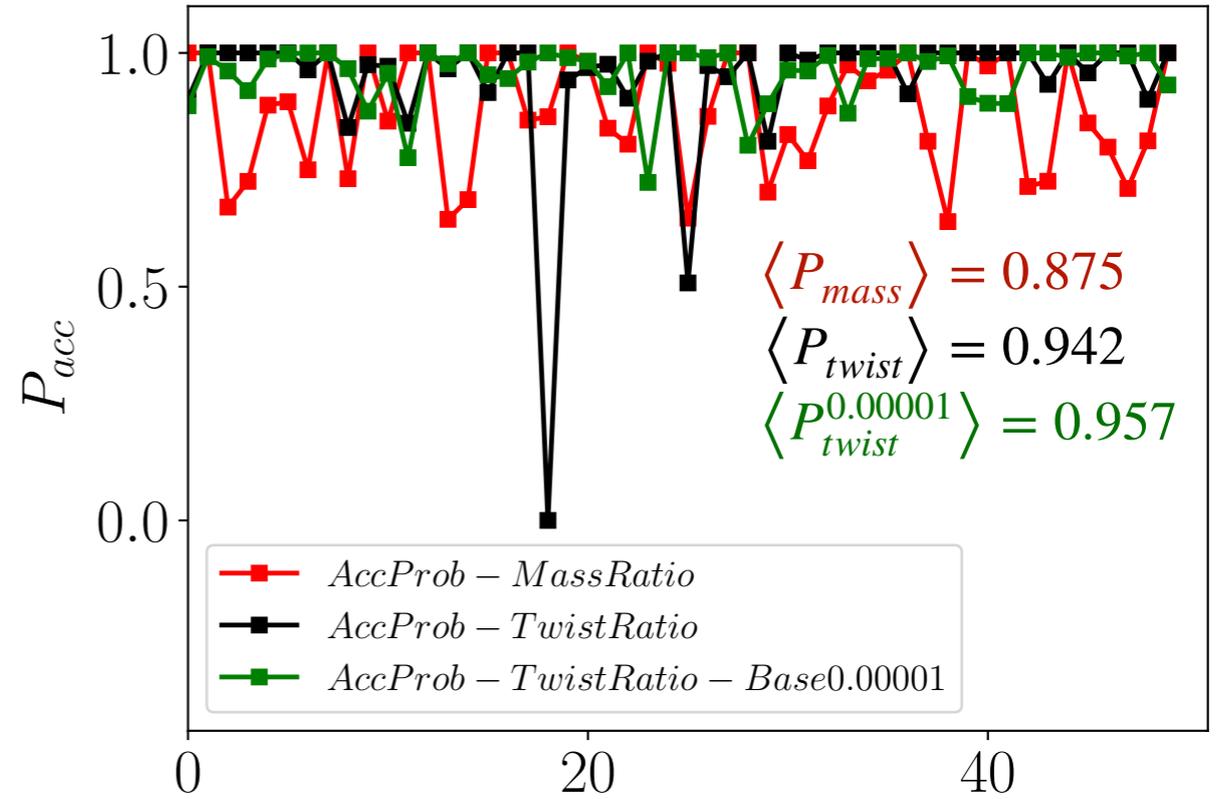

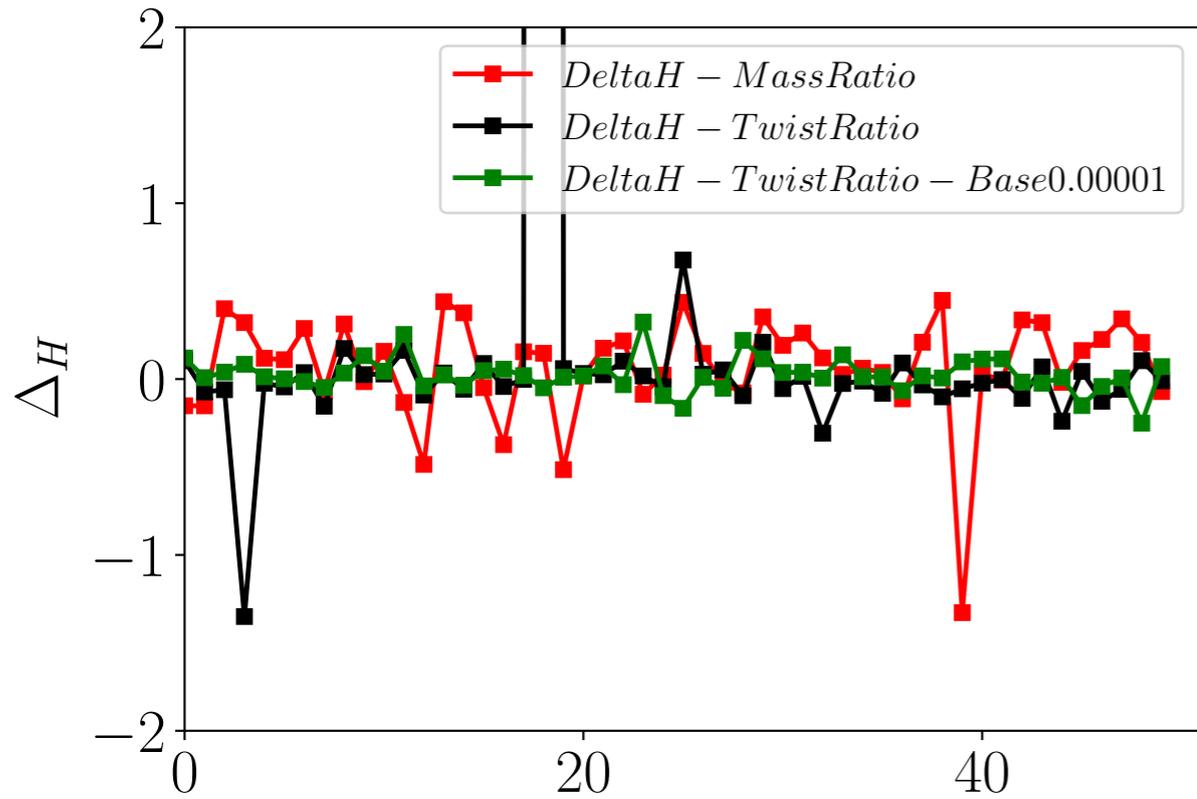

Maximum Fermionic Force – Ratio Term F_{max}

Fermionic Force – Cancel Term F_{cancel}

MD Integration Stability

Summary

- What we have
 - Asymmetric/Symmetric e/o preconditioning
 - Hasenbusch mass/twist ratio preconditioning
 - Multigrid for twisted operator (currently symmetric e/o)
 - Multiple time scale MD integrator
 - High order MD integrator (e.g. force gradient)
 - Adding twist in the MD integration can stabilize HMC
- Outlook
 - Strategies for parameters tuning
 - Optimize trajectory wall time
 - Coarse grid deflation
 - Multiple right-hand side solver
