# Optimisation of the Inner Detector tracking for the ATLAS High Level Trigger

Mark Sutton

University of Sussex

on behalf of the

ATLAS Collaboration

28<sup>th</sup> October 2020

## Preface

- The Inner Detector Trigger is an essential component of the ATLAS Trigger
- Without it, it would be impossible to achieve the required rate reduction with sufficient purity to fulfil the ATLAS physics programme
- Example  $H \rightarrow 4$  lepton analysis, only possible because of the high performance of the leptonic triggers
  - Every event used in the analysis was accepted following the successful reconstruction of the leptons in the trigger

# Rubric

- Was requested to address some specific questions ...
  - How the resource estimates for online reconstruction were obtained and then validate
    - To what extent this can be extended to an e+e- experiment
  - What the implications are for interfacing 'real time world' to 'offline world' In terms of software techniques and DAQ
  - Any ATLAS extrapolations for the cost of HLT processing into the future
- Will attempt to address each of these, to a greater or lesser extent

# The ATLAS Trigger and Filter-like Inner Detector

- Precision Tracking • The Inner Detector (ID) consists of a **PIXEL** detector, microstrip detector (SCT) silicon detectors, and a straw tube transition radiation detector (**TRT**)
- Level 1 runs fast reconstruction with dedicated limited granularity detector readout (Calorimeter and Muon Spectrometer and Muon Spectrometer
  - Identifies Regions of Interest (RoI) for processing in the HLT with full detector granularity Reconstruction and Hypo
- Silicon detector readout not fast enough for use in Level 1 ...
  - Used for the first time in the DAQ chain in the High Level Trigger (HLT)

Calorimeter.

40 MHz bunch crossing

> **:ctor (ID)** is the ATLAS sub-detector ack and vertex reconstruction

## **Jb-systems**

tor – closest to beam line and oint of barrel and endcap silicon pixel , and.. e B layer (IBL) ←added in Run2 ctor tracker (SCT) and 9 endcap layers of silicon micro-29/07/2020 Jules

d endcap modules of straw drift

M Sutton - ATLAS ID Trigger optimisation

# Offline to online ...

- General desire to run trigger reconstruction as close to the offline reconstruction as possible
- For LHC Run 1 (2009 2013) ran a two level HLT
  - Level 2 running faster, but less accurate track reconstruction
  - Event Filter (the third trigger level) running a modified version of the offline tracking - EFID

ms

шe

cbn

- Reruns data preparation
- Offline pattern recognition
- Offline ambiguity solver including offline track fit
- For Run 2 (2015-2018) L2 and EF stages combined into a single HLT stage
- Avoid running the data preparation and pattern recognition a second time
  - More than 50 % of CPU in the offline algorithm in pattern recognition
  - Doesn't scale well with pileup multiplicity around 50 60 interactions per bunch crossing at the start of a fill in Run 2
  - Too slow for the trigger

pileup interaction multiplicity

# Improvements to the offline tracking

- Offline tracking itself is costly
  - After trigger selection, events written to offline storage and subject to the full offline reconstruction in the ATLAS Tier 0
  - Offline reconstruction must not fall too far behind data taking from the detector
  - Although not time critical in the same way as the trigger tracking, is a limiting factor in the Tier 0 reconstruction
- For Run 2 there were improvements in the offline execution time:
  - Improvements to the computing infrastructure:
    - Switch to running on a 64-bit, rather than 32-bit kernel
    - Newer compiler, switched to gcc 4.8 from 4.3
    - Modifications to the algorithm execution, replacement of the CLHEP [45] linear algebra library by the Eigen library
- These immediately lead to benefits for the Trigger EFID tracking, but still rather too slow for trigger use
- A new strategy was needed for Run 2

## Run 2 tracking strategy

- New strategy for Run 2: redesigned the fast L2 reconstruction for use in the single stage HLT:
  - Fast track reconstruction customs seeding but with offline track following
  - Seed the offline ambiguity solver with the tracks from the fast reconstruction as explained in the ID Trigger overview
- Custom Fast tracking and seeding gives significant reduction in CPU with respect to the Run 1 strategy, running the offline pattern recognition

- Adopt a two stage approa
- Overall time to run the act

M Sutton - ATLAS ID Trigger optimisation

# Additional offline considerations

- Other offline consideration that need modifying
  - Offline reconstruction has a first express stream pass limited event sample, useful for determining
    - Track based alignment and determination of the beam line position ( beam position moves throughout a run ), instantaneous luminosity
    - Subsystem Calibration
    - Determination of dead or inactive modules, hot cells etc
- ATLAS used the concept of the **Luminosity Block** 
  - Fixed duration block of luminosity ~ typically 1 or 2 minutes over which the detector conditions are assumed to be constant
    - Calibration constant, alignment etc determined per Lumi Block
- Of course, cannot use the detector calibrations per Lumi Block during data taking as the data has not been processed
  - More limited use of detector conditions and alignment most up to date version fixed at start of the physics run
- A notable exception is the **beamspo**t algorithm ...

10

# The beamspot and luminosity

- $\bullet$
- •
- •
- For beamspot, have a dedicated beamspot chain, with its own instance of the tracking

# Resource estimation

- Lots of algorithm execution times shown so far, but where do they come from ? How do we estimate required CPU resources to ensure we can to run the tracking ?
- Trigger cost monitoring
  - Used to monitor the execution time for each algorithm run as a step in the overall trigger processing
- Nightly tests
  - For every nightly build for the code release, run tests for each signature ( $\sim 40$ ), with multiple Monte Carlo samples
  - Internal timers for the different stage of processing, overall algorithm execution times from the cost monitoring
  - Allows full spectrum evaluation for any change in the code quickly identifies losses in efficiency or slower algorithm processing for any code changes
  - Detailed performance estimates for the efficiency and resolution
- Data taking from the ATLAS detector
  - Cost monitoring times all algorithms, samples 1 in every 10 event processed by the HLT
  - Timing information written to the event stream for later reconstruction off line
  - Monitoring HLT Farm occupancy in detail number of cores occupied at any one time, events waiting to be processed etc - establish operation points for future running
- Trigger reprocessing
  - events input to the HLT

• For example, if an algorithm takes 1 second to execute, but only in 10 out of every 1000 events, that is only a 10 ms average contribution to the total processing time

• Runs the trigger offline on the grid - data from special Enhanced Bias runs with effectively a large HLT trigger pass through rate used to give realistic spectrum of

# Nightly tests - id trigger branch view

# Enhanced bias data

### PUB-TRIG-2016-02

- In practice five dedicated HLT chains are added to the menu for the Enhanced Bias data with a large pass through rate
  - Approximately 300 Hz of additional triggers for 1 hour in the run, for around 10<sup>6</sup> Enhanced bBias events
  - Trigger menu is invertible ie a single event weight  $w_{\rm EB}(e)$  can be computed for each individual event to correct for the prescales  $w_C(e)$  for the chains used at Level 1 and restore the zero bias spectrum

$$\operatorname{Rate}(c) = \frac{\sum_{e=1}^{N} w_{\mathrm{EB}}(e) w_{C}(e)}{\Delta t} \qquad \frac{1}{w_{\mathrm{EB}}(e)}$$

• with raw chain rate  $r_{je}$  for each of the EB chains with prescale  $p_j$ 

Name	Seeding	Output [Hz]	L1 Seed Rates [kHz]
Random	Random	60	> 500
Low	Random	60	50–500
Medium	Random	60	20–50
Primary	Direct	110	0.1–20
High	Direct	10	< 0.1

- When reprocessing the data on the grid, the events are all processed with no prescale for rate estimation, but with prescale for CPU estimation
- Subsequently, any set of prescales can be applied to the rates from each trigger to estimate the actual trigger rate for that percale set

$$= 1 - \prod_{j=1}^{\text{EBChains}} \left[ 1 - \frac{r_{je}}{p_j} \right]$$

![](_page_15_Picture_15.jpeg)

![](_page_16_Figure_0.jpeg)

# Rate and CPU estimation

- The overall rates can be estimated with some degree of accuracy
- For CPU estimation, prescales should be applied during execution, sine the trigger caches the results for an algorithm running in an RoI if that RoI has already been processed by that algorithm for a different chain
  - Need to get the number of times each Rol is processed correct, else the overall time all be incorrect
  - Converting the prescale corrected processing mean time per event to a rate estimate can determine the mean number of processor cores required to execute a given HLT chain, or full menu

17

# Outlook

- For the Run 3, had planned to make use of hardware accelerated tracking the Fast Tracker (FTK), which was however cancelled
  - Attempting to extend the software ID Trigger to address the use cases which would have benefited from the hardware tracking
  - Currently modifying the ID Trigger code and evaluating the performance to see how fast we can make it
    - Also complete redesign of the ATLAS software framework to run multi threaded code Gaudi Hive
  - The cost monitoring is being used to evaluate the performance, and all the tools described used to estimate the required resources wit the new software
    - Still reasonably early days
      - Code still under development
      - Trigger Menu still evolving
    - Estimates available within the ATLAS collaboration but until everything has stabilised, too soon to present to the wider community
- What lessons would we learn for the future ?
  - the ID Trigger
  - Frequent reprocessing of Enhanced Bias runs is essential for estimating the overall CPU load for the full Trigger Menu, with realistic prescales
  - Important to understand the behaviour as a function of the pile up combinatoric algorithms do not scale linearly with pile up
  - Early rejection in the trigger is important can experiment by the movement of different algorithms, most costly algorithms should be executed less frequently
    - Can be run in smaller regions for preselection to achieve even faster execution
- All of these would be important for any experiment, with any trigger
  - rate trigger system

• Nightly testing is very important for the very fine grained study of the performance, and execution times for the individual algorithms across the entire trigger, not just

• Perhaps the behaviour with larger pile up is less relevant for a lepton collider, but detailed evaluation and estimation of CPU load will be very important for any high
