

Acknowledgements

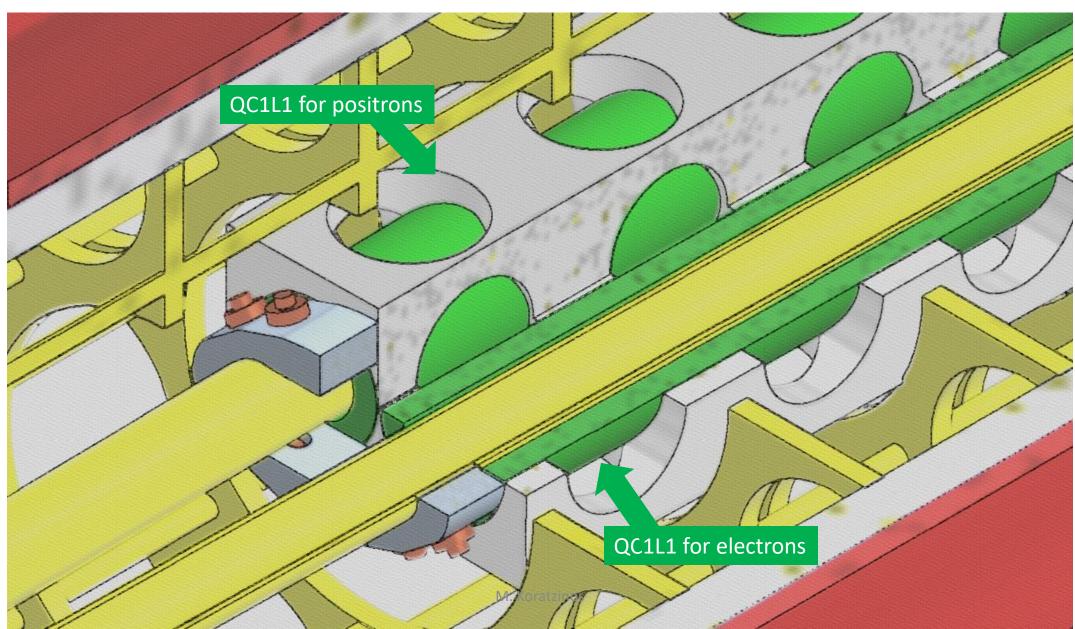

- For the design: Glyn Kirby, Jeroen van Nugteren (author of Field)
- Manufacturing: the CERN main workshop, Karol Scibor
- Bits and pieces: the B927 boys, Pierre-Antoine Contat, Jacky Mazet
- Winding and assembly: Herman ten Kate's team in B180, Tim Mulder
- Special tools manufacturing: the CMS workshop in P5, Maf Alidra
- Warm testing: the B311 boys Carlo Petrone, Melvin Liebsch, Dmitry Akhmedyanov, Stefano Sorti
- This work would not have been possible without the support of many people. I would like to especially thank Austin Ball, Katsunobu Oide, Frank Zimmermann, Guenther Dissertori, Michael Benedikt

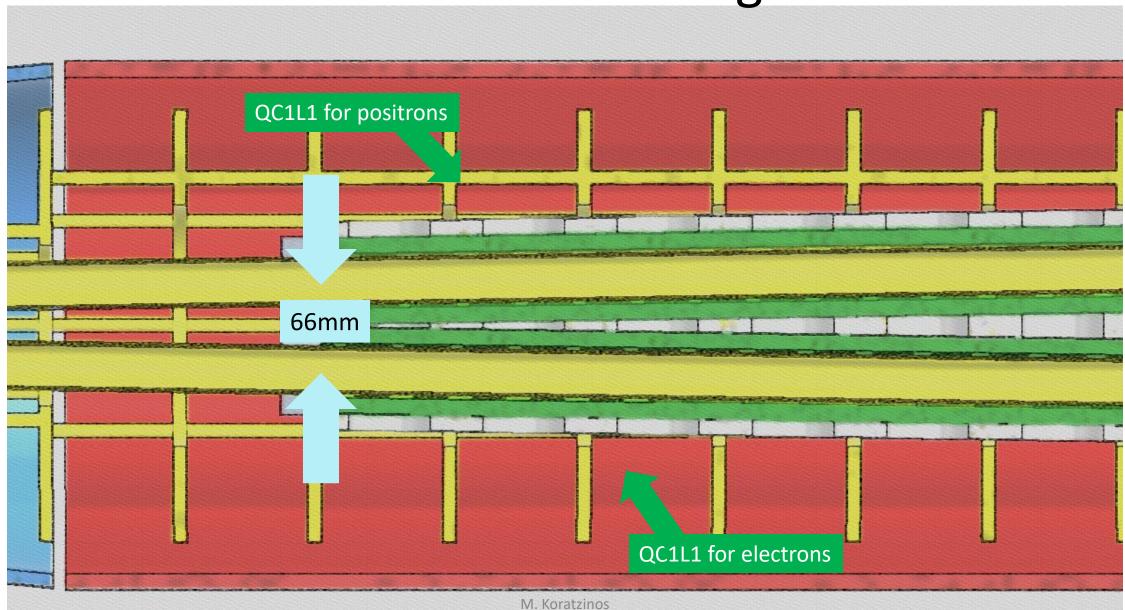

Final focus quadrupoles

- Two main units on each side of the IP and for each beam, e^+ (P)and e^- (E): QC1LE, QC2LE, QC1RE,QC2RE, QC1LP, QC2LP, QC1RP,QC2RP
- QC1 is inside the detector and itself comprises three units per side per beam: QC1L1P, QC1L2P,QC1L3P,
 QC1L1P, QC1L2P,QC1L3P, QC1L1E, QC1L2E,QC1L3E, QC1L1E, QC1L2E,QC1L3E
- There are 5X2X2=20 single aperture units in total

From the FCC CDR update 13/12/2019, Katsunobu Oide

| | Start position | Length | B' @Z | B'@W | B' @ H | B' @ tt |

- Optics design is such that E and P quads have the same strength
- Maximum strength is 100T/m
- The most difficult element is QC1L1, the closest to the beam and where the E and P quads are closer together

The updated parameters are rather different for QC1L1: its length is now 70cm from 120cm

M. Koratzinos

Main challenges

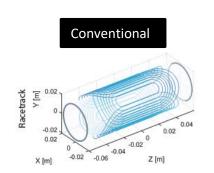

- Lack of space: 66mm between the two beams at QC1L1. Quads are at an angle so crosstalk varies along the length
- Required field quality: better than 10⁻⁴ and of O(10⁻⁵)
- Need to eliminate crosstalk between the two quadrupoles
 - The beam pipe inner diameter is 30mm
 - The beam pipe is warm, so we need vacuum insulation and cooling/heating for the beam pipe
 - The minimum size of the thickness of the double layer beam-pipe with the cooling liquid flowing in-between is 3mm
 - We are then leaving 2mm for vacuum and a heat shield
 - → aperture of FF quads is 40mm
 - ⇒ space left for former, conductor, yoke = 13mm
 - → it would be very difficult to fit an iron yoke with reasonable thickness to eliminate crosstalk

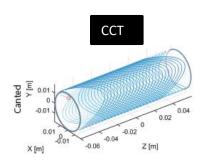

Choice of technology for QC1L1

- There is only one technology we have identified that can tackle those challenges: a CCT iron-free design
- A CCT design can compensate for the crosstalk between quadrupoles even in the case that crosstalk changes every centimetre: see M. Koratzinos et al. 1709.08444 [physics.acc-ph] Published in: IEEE Trans. Appl. Supercond. 28 (2018) 3, 4007305
- A CCT design can also compensate for edge effects ensuring excellent field quality locally at every point of the magnet. This is important since the optics functions vary wildly close to the IP

CCT accelerator magnets

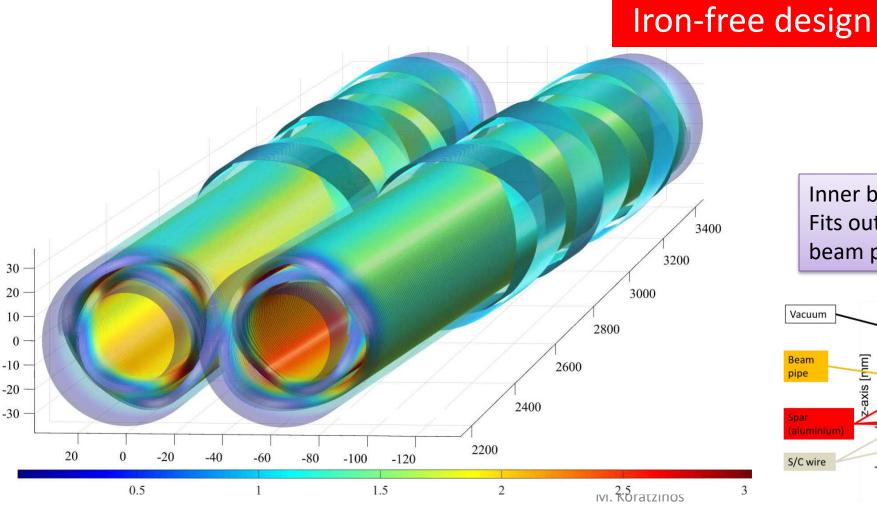

- A CCT (Canted Cosine Theta) is a type of accelerator magnet where the multipole mix is a *local* attribute of a magnet. (One can trivially design a magnet which is a dipole on one side and a quadrupole in the other.)
- The QC1L1 magnets are NOT quadrupoles. They are quads minus the field due to the other aperture. But together they make two nearly perfect quadrupoles
- Other important advantages of CCTs:
 - Cheap to make from the magnet design program to CAD to CNC machine with no manual interventions
 - Easy to make no pre-stress! Stress management is trivial in CCTs
 - Fast to make few steps, no expensive equipment
 - Excellent field quality please see further

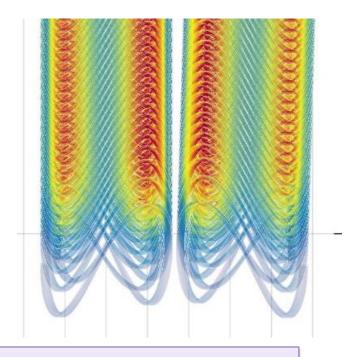

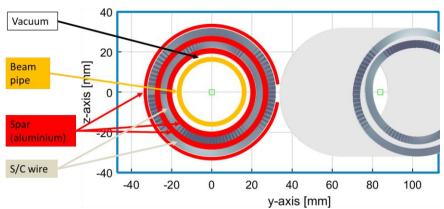

QC1L1

QC1L1 is the first and most demanding pair of quadrupoles of the final focus system of FCC-ee

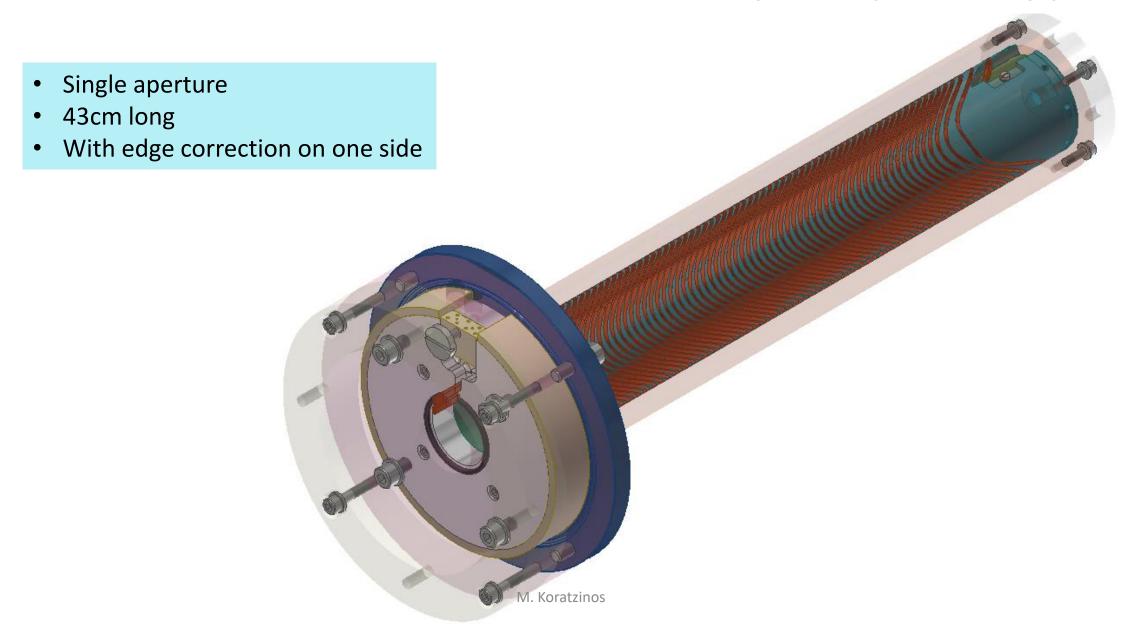

Inner bore: 40mm (diameter)
Fits outside the warm water-cooled
beam pipe of inner diameter 30mm

Why prototype?

- Although it works very well on paper, we need to test it in practice
- The first prototype is a single aperture magnet. So how can we test the crosstalk performance?
- The specific prototype employs a technique similar to the crosstalk compensation: edge correction
- One end of the magnet is corrected for local multipoles, which are present on every accelerator magnet design
- Exactly the same technique and tools are used for the crosstalk compensation of a double aperture design. → If the edge correction works as expected, so will the crosstalk compensation

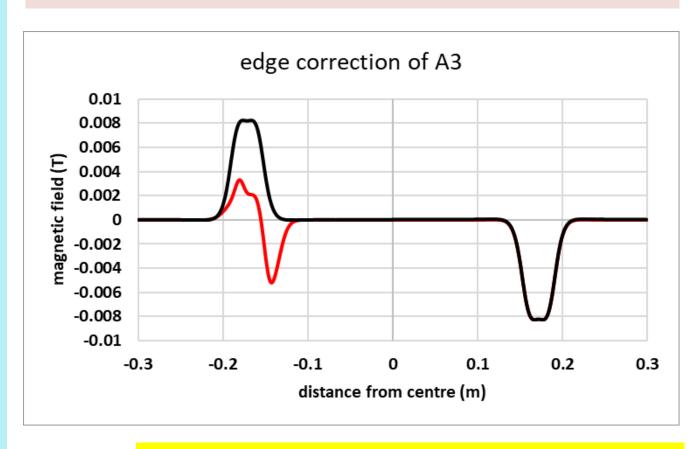

The FCC-ee Final Focus Quadrupole prototype

Local edge correction

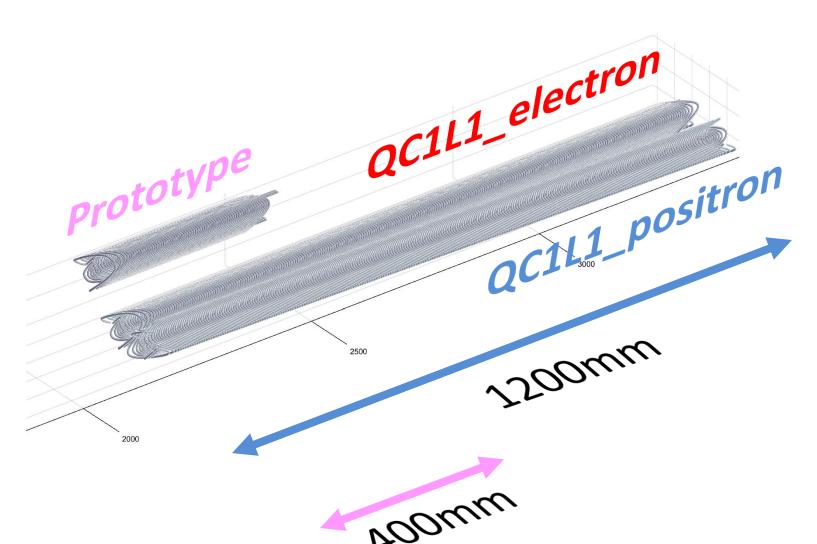

- By design, a CCT magnet has all integral multipoles vanish (with the exception of the main one).
- However, the skew (A) components of the magnetic field compensate only because they have opposite signs at the entry and exit of the magnet.
- QC1L1 sits in an area of rapidlychanging optics functions: the change of beam size between the entry and exit of the magnet is a factor of ~2. → a local correction is needed

Example: correction of A3 component, one side only. In red: corrected; in black: uncorrected

M. Koratzinos et al. 1709.08444 [physics.acc-ph]

QC1L1 and the prototype

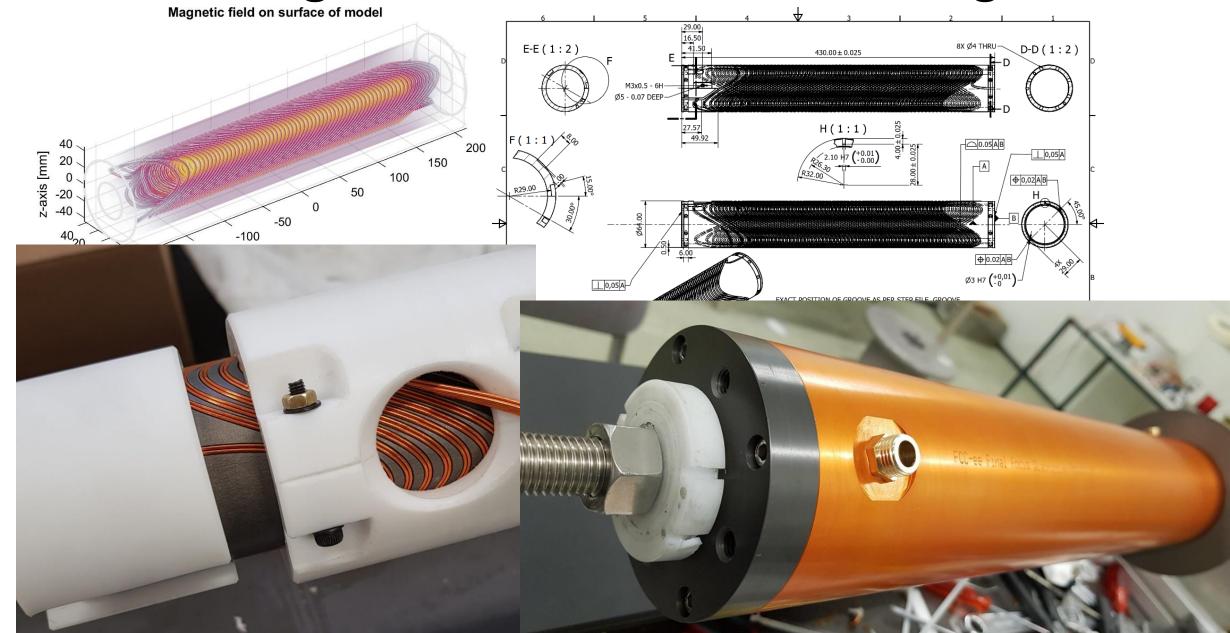

The first FCC-ee Final Focus prototype is a single-aperture version of QC1L1, with identical aperture (40mm) but one-third of the length (26% of the quadrupole strength). It has asymmetric edges

 $I_{max} = 725A$

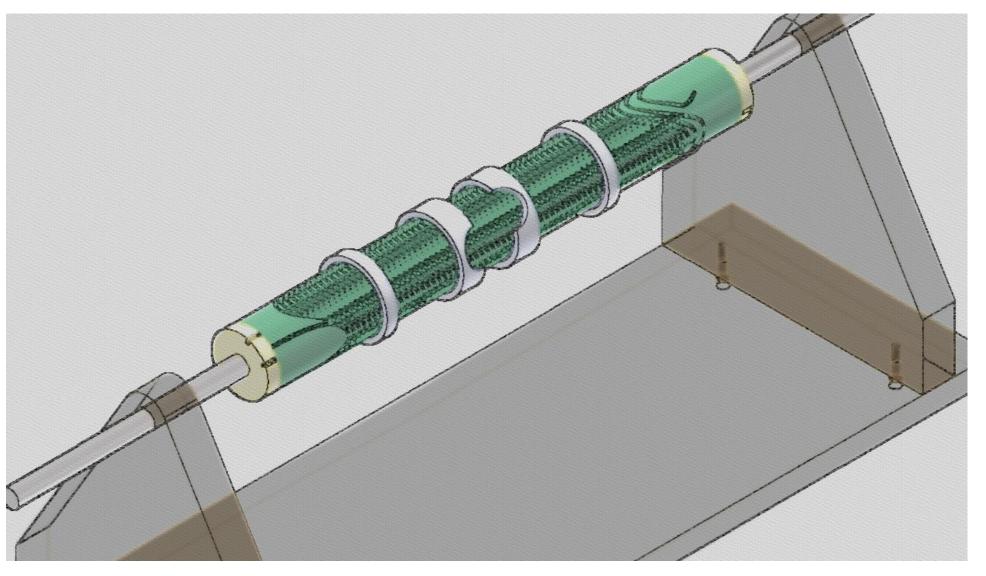

Max. gradient: 100T/m

Design, manufacture and winding

Winding

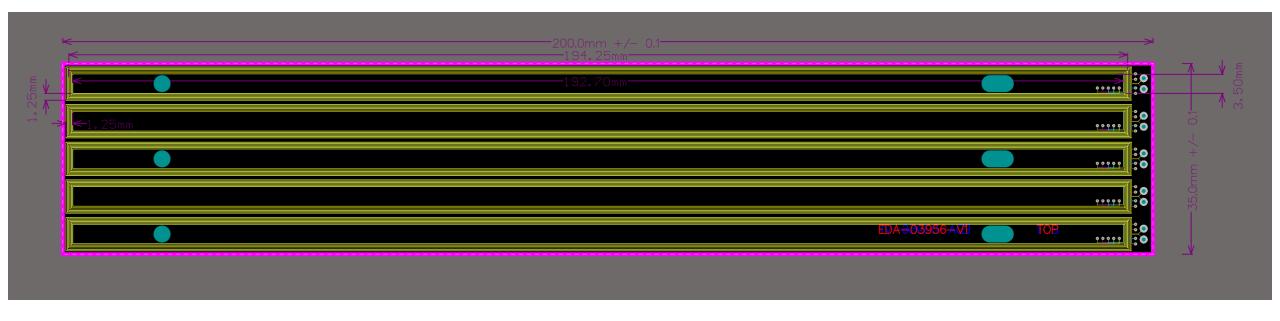

- Was done inhouse on a purpose built winding table
- Pre-stressing the conductor was not necessary

Testing at warm

- The first magnetic quality tests were performed at warm
- A rotating coil arrangement was used:
 - The magnet is powered with a current of 5 A (0.7% of maximum current) at room temperature
 - We measure the magnetic flux as the coil is rotated.
 - Each measurement is averaged over 100 revolutions
 - Then the data is post-processed to calculate the first 15 multipoles.
 - Then current is reversed and another (100-revolution) measurement is taken
 - The final numbers are the average over the two polarities This eliminates the contribution due to the earth's magnetic field and any other static fields.
- All measurements made at a radius of 10mm
- Rotating coil length: 200mm (194mm active), width 35mm
- The rotating coil can be moved to measure the (integrated) field at different areas of the magnet: the middle, the corrected side and the uncorrected side

The rotating coil

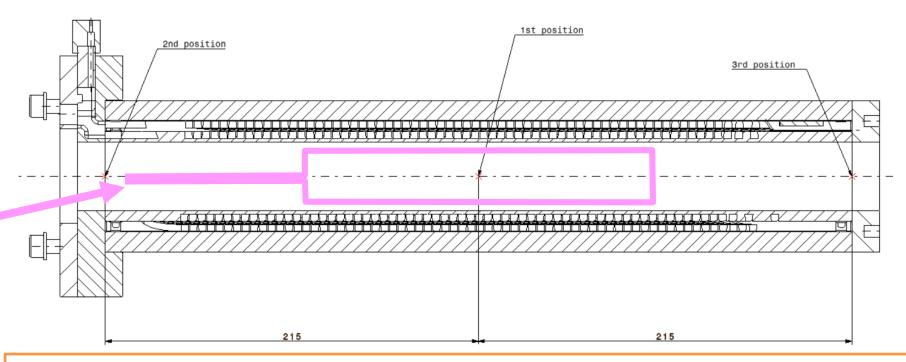

Length is 200mm nominal, 194.25 mm active, width is 35mm, split in five individual coils

- For the quadrupole magnet, the individual coils are combined in such a way, that the coil is immune to the B2 field component, which is the dominant one, to be able to see errors in higher multipoles
- For the transfer function measurement, the coil is combined linearly

Testing arrangement

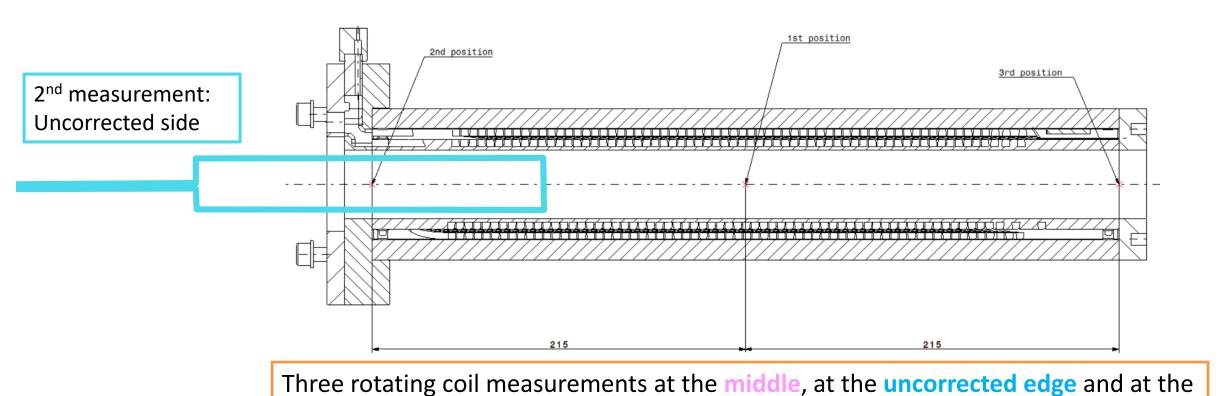

1st measurement: Centre

Rotating probe

Three rotating coil measurements at the middle, at the uncorrected edge and at the corrected edge

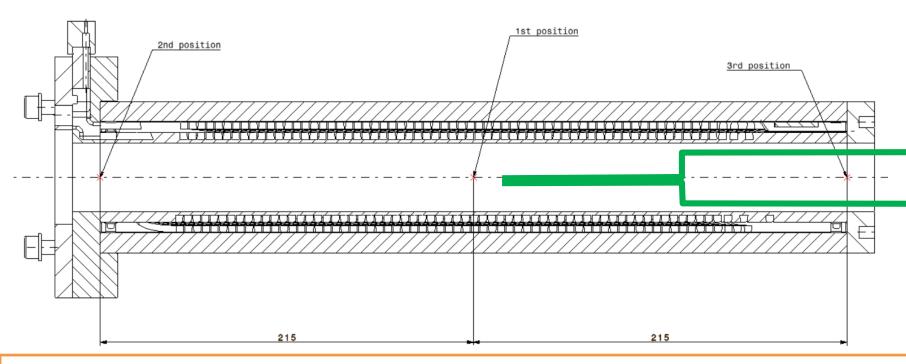

Testing arrangement

corrected edge

Testing arrangement

3rd measurement: Corrected side

Three rotating coil measurements at the middle, at the uncorrected edge and at the corrected edge

Measurement video

Nomenclature

Magnetic field of accelerator magnet:
$$B_z = \sum_{n=1}^{\infty} (B_n + iA_n) \left(\frac{Z}{R}\right)^{n-1}$$
, $z = x + iy = re^{i\theta}$

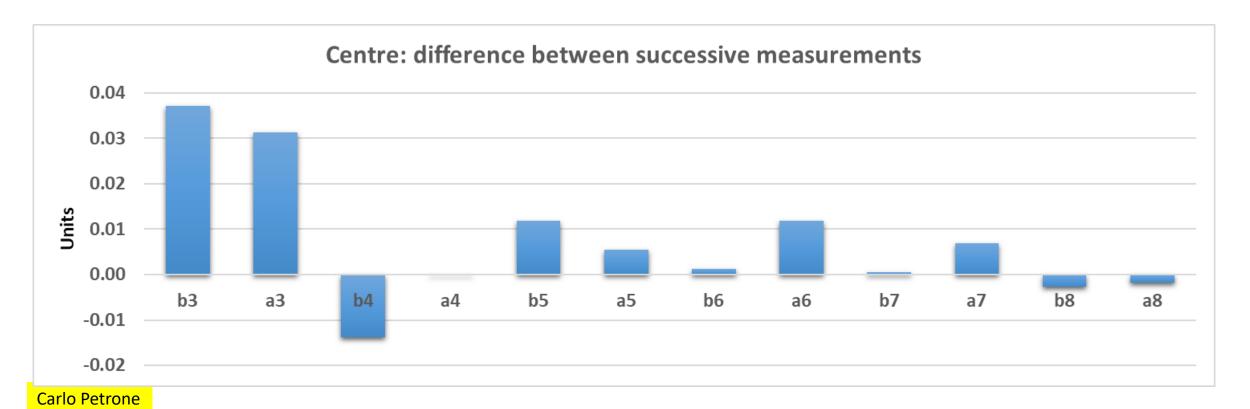

The way that results are traditionally presented is as follows:

- a_n, b_n are the multipoles of order n (n = 1 : dipole; n = 2 : quadrupole; n = <math>3 : sextupole, etc.) they are measured in units of 10^{-4}
- a_n are the skew components, b_n the normal components
- Definitions:
 - $-b_n = \frac{B_n}{B_2} \times 10,000$ @ R = 10mm where B_2 is the dominant, quadrupole component
 - Same for the skew components: $a_n = \frac{A_n}{B_2} \times 10,000$ @ R = 10mm
- Traditionally R is chosen as 2/3^{rds} aperture. Our beam pipe is 15mm radius, so we measure at 10mm

Repeatability of measurements

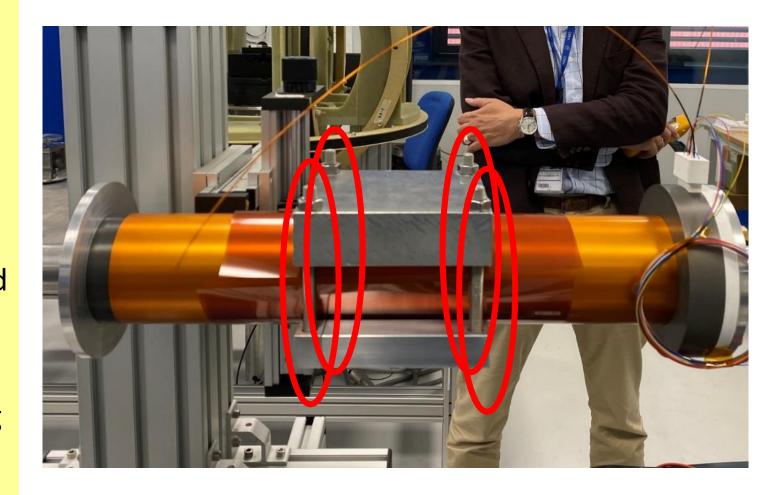

The first test is the (short-term) reproducibility of measurements: The plot shows two successive measurements. Repeatability is excellent, within 0.04 units or better

→ The sensitivity of the method is at the ~0.02 unit level

Centre measurement

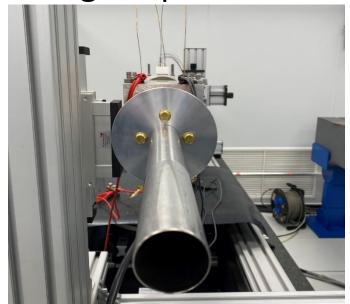

- We need to make sure that whatever we measure is due to the magnet and not its environment
- Although the mechanical clamping of the magnet is with aluminium claws, we have also used stainless steel high-strength bolts
- At this level of precision, we need to guard against these bolts distorting the field and therefore introducing multipoles
- Do not forget that we are dealing with 10⁻⁵ effects

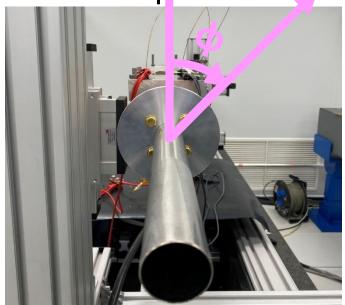

A strategy for measuring the pure magnet components

- We decided to take two measurements: one with the magnet in its proper position and the second where the magnet is rotated by ~45 degrees. (suggested by Glyn Kirby, CERN)
- The multipole errors due to the magnet should rotate with the magnet, but the errors due to the environment should not
- We then have two measurements and two ur knowns

Original position

rotated rosition

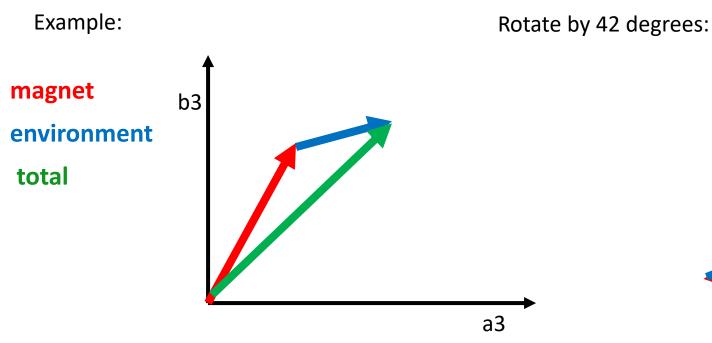

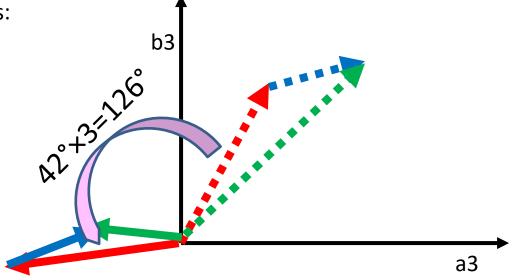

In our case, φ was measured to be 41.87 degrees

Rotated/original measurements

| | b3 | a3 | b4 | a4 | b5 | a5 | b6 | a6 | b7 | a7 | b8 | a8 |
|-----------------------|-------|------|------|------|-------|-------|------|-------|------|-------|------|-------|
| Original data (units) | -0.24 | 0.30 | 0.54 | 0.54 | -0.17 | -0.03 | 0.64 | -0.12 | 0.03 | -0.01 | 0.00 | -0.03 |
| Rotated data (units) | 0.08 | 0.43 | 0.49 | 0.66 | -0.16 | -0.03 | 0.65 | -0.11 | 0.03 | 0.00 | 0.00 | -0.03 |

If a multipole component comes from the magnet and not from the environment, it is expected to change under this rotation.

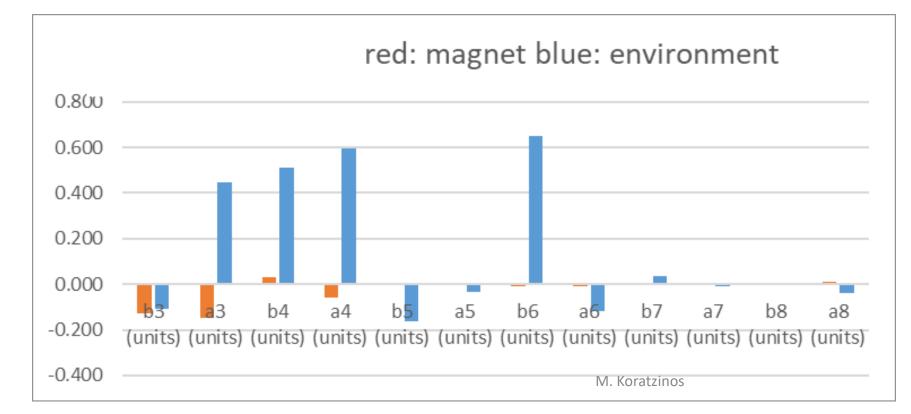

Vector rotates by (rotation angle) × n

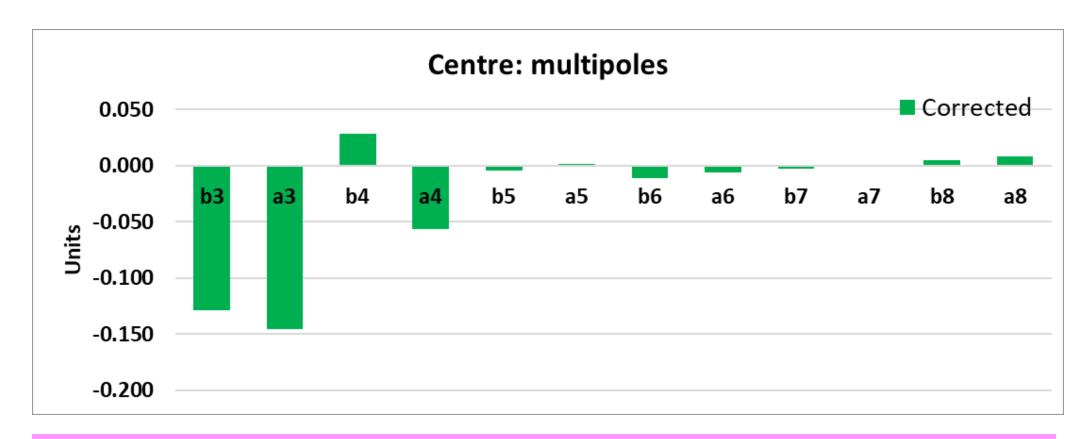

Results

| | b3 | a3 | b4 | a4 | b5 | a5 | b6 | a6 | b7 | a7 | b8 | a8 |
|-----------------------|--------|--------|-------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Original data | -0.24 | 0.30 | 0.54 | 0.54 | -0.17 | -0.03 | 0.64 | -0.12 | 0.03 | -0.01 | 0.00 | -0.03 |
| Rotated data | 0.08 | 0.43 | 0.49 | 0.66 | -0.16 | -0.03 | 0.65 | -0.11 | 0.03 | 0.00 | 0.00 | -0.03 |
| Magnet component | -0.129 | -0.146 | 0.029 | -0.057 | -0.004 | 0.001 | -0.011 | -0.006 | -0.003 | 0.001 | 0.004 | 0.009 |
| Environment component | -0.110 | 0.447 | 0.510 | 0.595 | -0.163 | -0.035 | 0.652 | -0.118 | 0.033 | -0.008 | -0.005 | -0.036 |

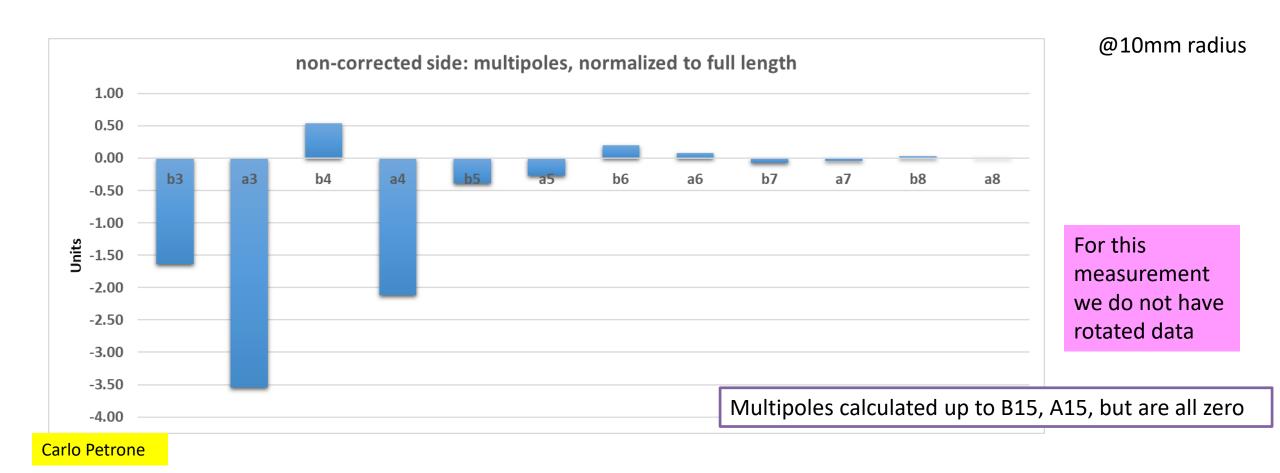

A big chunk of the measured multipoles can be attributed to the environment

Results - centre

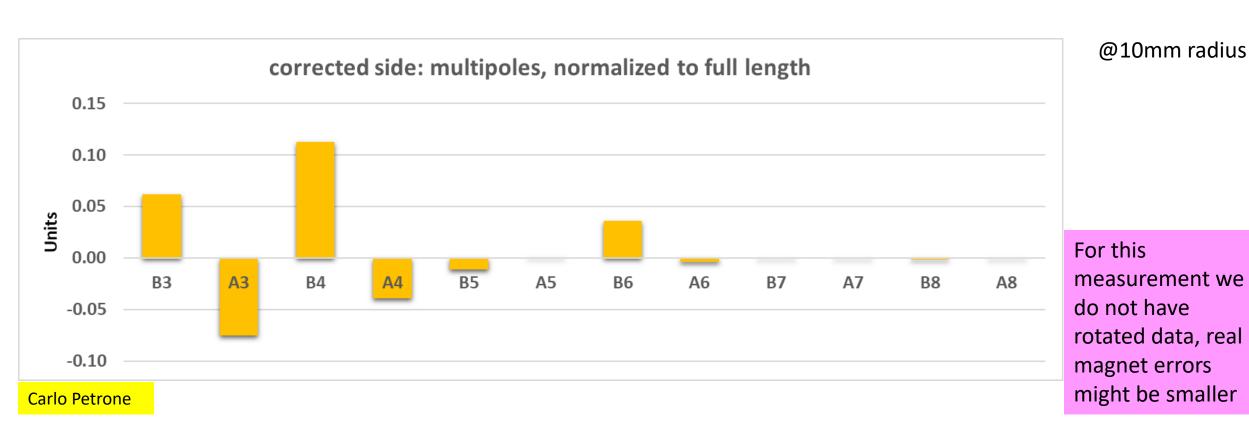

All multipoles are below 0.15 units and only b3, a3 is above 0.10 units. (this is barely above the sensitivity of the method)

Field quality at the edge, without correction

3.5 units in A3, 2 units in A4

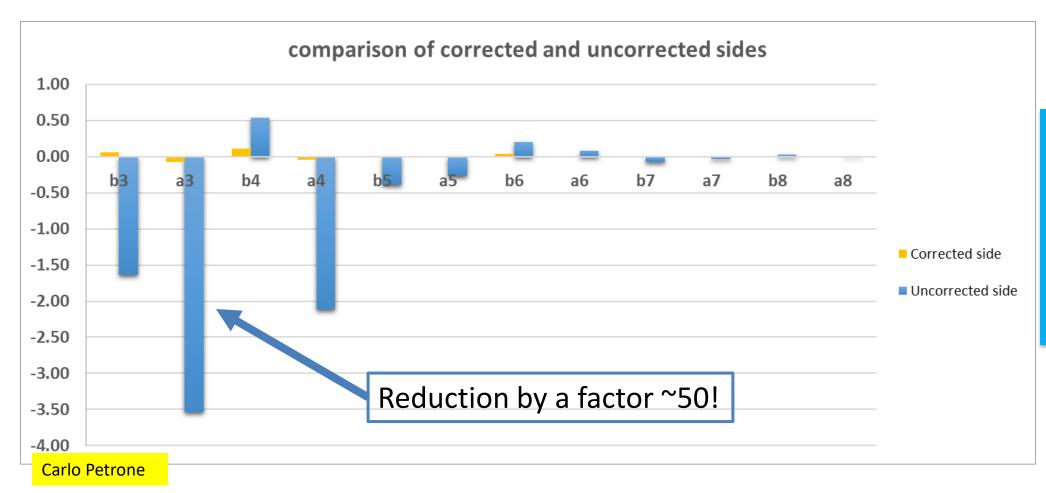

Field quality at the edge, with correction

0.1 units maximum. An excellent result.

Multipoles calculated up to B15, A15, but are all zero

Field quality at the edge, comparison

Corrected side has edge effects that are 0.1 units or less

For both plots, the normalization is to the full length of QC1L1 (1200mm)

Edge correction really works!

Conclusions

- The first FCC-ee final focus prototype has been designed, manufactured and the first tests at warm are available.
- Field quality is excellent.
- All multipoles in the middle of the magnet are 0.15 units or less, approaching the accuracy of the method. These are real measurements, not simulation!
- The novel technique of locally correcting each edge for edge effects is working beautifully → this gives us confidence that the crosstalk compensation will also work.
- All multipoles of the corrected edge contribute 0.1 units or less. → this is a "perfect edge" magnet.
- The CCT iron-free technique is very well suited for the final focus quadrupoles of FCC-ee (and also CEPC...).
