How arbitrary are perturbative calculations of the EWPT?

- Electroweak symmetry is broken in today's Universe, but was restored at very high temperatures.
- The transition between the symmetric and broken phases, the Electroweak Phase Transition (EWPT), is relevant to
  - Explanation of the baryon asymmetry of the Universe.
  - Generation of detectable gravitational wave.
  - Dark Matter relic density.
  - Vacuum stability.

- > All these calculations need information about the minimum of the Higgs potential, such as their positions, first and second derivatives, and barriers among them at any temperature.
- > The perturbative effective potential is usually used in new physics studies.
- At one-loop level, it is given by

 $V_{\text{eff}}(\phi, T) = V_0(\phi) + V_1(\phi) + V_{1T}(\phi, T) + V_{\text{ring}}(\phi, T)$ 

As has long been recognized, the one-loop effective potential depends on 

- gauge and gauge fixing parameter  $\xi$ ,
- renormalisation scheme and renormalisation scale,
- remedy of infrared divergences caused by Goldstone boson loops,
- and treatment of daisy diagrams.
- temperature approximation is also widely used.

## Transition property

Here we investigate the extent to which perturbative calculations of the electroweak phase transition are arbitrary and uncertain, owing to above choices, by showing the impacts on the critical temperature  $T_c$  and the transition strength  $\gamma_{\rm EW}$  in xSM.

#### Model

We use the SM extended by a real scalar singlet (SSM) with  $\mathbb{Z}_2$  symmetry as our benchmark model,

$$V_0(H,S) = -\mu_h^2 H^{\dagger} H + \lambda_h (H^{\dagger} H)^2 - \frac{\mu_s^2}{2} S^2 + \frac{\lambda_s}{4} S^4 + \frac{\lambda_{hs}}{2} H^{\dagger} H S^2$$

because there are only three free independent parameters,  $m_s$ ,  $\lambda_s$ ,  $\lambda_{hs}$ , and there is only one first order phase transition in the evolution history of the Universe.

### Gauge dependence

> We show the  $\xi$  dependence of the  $T_c$  and  $\gamma_{\rm EW}$  in the  $R_{\xi}$  and covariant gauges for different methods, using a benchmark point of

 $\lambda_{s} = 0.1, \lambda_{hs} = 0.3$  and  $m_{s} = 65$  GeV.

- The PRM and HT methods which, of course, are independent of the gauge parameter  $\xi$ .
- In the  $\overline{\text{MS}}$  scheme, with  $\xi$  increasing, the critical temperature  $T_c$  increases slightly for small values of  $\xi$ , and then decreases significantly for large values of  $\xi$ .
- The choice of treatment of the GC has limited impact.
- Results from the covariant and  $R_{\xi}$  gauges are identical at  $\xi = 0$ .

## Gauge dependence

- > However, there may be constraints on perturbativity that impose  $\xi \leq 1$ .
- Varying the gauge between  $\xi = 0$  and 1 results in only slight changes in the properties of the FOPT.
- Some methods do not depend smoothly on  $\xi$ .
- Although using the modified  $\mu$  from one-loop tadpole cures the GC at  $\xi = 0$ , the Goldstone may be massless at tree-level in the one-loop vacuum for other values of ξ.
- In the covariant gauge the  $T_c$  increases or decreases almost linearly with  $\xi$  increasing. This is because we take the real part of the square root in masses and for sufficiently large  $\xi$ , the  $\xi$ -dependent parts are imaginary.

- ► The renormalisation scale dependence of the PT properties originates from the scale-dependence of the one-loop corrections to the effective potential.
- > We show the renormalisation scale dependence in the MS scheme and PRM methods, by varying the renormalisation scale from  $Q = \frac{1}{2}m_t$  to  $Q = 2m_t$ .
- ► In each of the panels, we vary one input parameter around the benchmark point
- We see almost no parameter dependence in the results at  $\lambda_{hs} \leq 0.2$  and  $m_s \gtrsim 90$  gev.
- A common and important feature in all the results is that the uncertainties rise sharply when the critical temperature is sensitive to the Lagrangian parameters.

To obtain  $T_c < 5$  GeV, the model parameters have to be tuned to one part in 10<sup>7</sup>.

$$\Delta V(T=0) = -\frac{1}{4}\frac{\mu_s^4}{\lambda_s} + \frac{1}{4}\frac{\mu_s}{\lambda_s}$$

- With RGE running and the Parwani method,  $\Delta_O T_c$ in the  $\overline{\text{MS}}$  result are about 16 GeV for large  $T_c$ .
- $\Delta_O T_c$  of the  $\overline{\text{MS}}$  scheme without RGE running is smaller than the one with RGE running, which is counter-intuitive.
- It is because the cancellation is spoilt by next-toleading order terms, since we apply two-loop RGEs and omit the anomalous dimension.
- $\Delta_O T_c$  of the PRM method with RGE running is rather small, typically about 5%. Without RGE running,  $\Delta_O T_c$  can be larger than 15%, and increases rapidly with  $T_c$  decreasing.

### Conclusions

- > We refrain from making recommendations about the best choices, and instead wish to emphasize the sizes of the uncertainties and which choices influence the results the most.
- The scale dependence in the  $\overline{MS}$  scheme and gauge dependence were the most significant sources of arbitrariness.
- $oldsymbol{O}$
- the choice of gauge and scale.
- from the  $\overline{\text{MS}}$  method.
- temperature by less than about 10 GeV.
- catastrophes still occurred for other choices of  $\xi$  for which Goldstones were massless in the EW vacuum.

How arbitrary are perturbative calculations of the EWPT?

> We investigated the impact of choices in the perturbative effective potential on the properties of first-order phase transition.

Scale dependence was particularly severe in the PRM scheme, and only somewhat alleviated by using RGE running.

• Whenever the PT properties strongly depend on the choices of Lagrangian parameters, they inevitably strongly depend on

• The gauge-independent PRM and HT predictions for PT properties were similar to each other and quite different from those

• The impact of the different treatments of daisy diagrams and the GC were relatively small, always changing the critical

• In the  $R_{\xi}$  gauge, we can avoid the GC at  $\xi = 0$  by using the Higgs mass squared parameter obtained from one-loop tadpole conditions in the calculation of the field-dependent Goldstone masses. However, even with this approach, Goldstone
