## Annual $^{10}\text{Be}$ record in travertine covering 1510-1701: a new proxy for reconstructing annual solar activity

*Wednesday, 23 October 2024 10:00 (20 minutes)*

Previous research has revealed that the  $^{10}\text{Be}$  record in laminated travertine has significant potential for reconstructing past high-resolution solar activity. However, the depositional processes of atmospheric  $^{10}\text{Be}$  into travertine have not been entirely resolved, therefore the methodology for extracting the production signal is not well established. In this study, we present an annually resolved  $^{10}\text{Be}$  record from Baishuitai travertine covering 1510-1701 CE, along with environmental proxies, discuss the potential influence of climatic/environmental variations on the travertine  $^{10}\text{Be}$  record, and propose an improved correction methodology for extracting the atmospheric  $^{10}\text{Be}$  production signal from the travertine. We show that  $^{10}\text{Be}$  deposition in travertines has two environmental impacts: the transport efficiency of atmospheric  $^{10}\text{Be}$  into travertine and the additional  $^{10}\text{Be}$  inflow from overland flow caused by rainfall. We demonstrate that these effects can be corrected based on iron and potassium contents, and the resulting corrected record reasonably agrees with ice-core and tree-ring data, indicating that  $^{10}\text{Be}$  in travertine can be a good proxy for probing the past annual solar activity.
