**RD(\*) anomaly:  
theoretical overview**

渡邊諒太郎 (渡边谅太郎)

**Ryoutaro Watanabe**

華中師範大學

CENTRAL CHINA NORMAL UNIVERSITY

# “Anomaly”

has been observed since 2012 in  $R_{D^{(*)}} = \frac{\mathcal{B}(\bar{B} \rightarrow D^{(*)} \tau \bar{\nu})}{\mathcal{B}(\bar{B} \rightarrow D^{(*)} \ell \bar{\nu})}$

## Measurements:

## SM process:

## Official consensus:

- $\sim 3\sigma$  deviation from the “official” SM value
- Some NP interpretations are possible, but not conclusive

# RD(\*): experiments

Experiment	$R_{D^*}$	$R_D$	Correlation
BaBar (2012)	$0.332 \pm 0.024 \pm 0.018$	$0.440 \pm 0.058 \pm 0.042$	-0.31
Belle (2015)	$0.293 \pm 0.038 \pm 0.015$	$0.375 \pm 0.064 \pm 0.026$	-0.50
Belle (2016)	$0.270 \pm 0.035^{+0.028}_{-0.025}$	—	—
Belle (2019)	$0.283 \pm 0.018 \pm 0.014$	$0.307 \pm 0.037 \pm 0.016$	-0.52
LHCb (2015)	$0.336 \pm 0.027 \pm 0.030$	—	—
LHCb (2017)	$0.280 \pm 0.018 \pm 0.029$	—	—
Previous average	$0.297 \pm 0.013$	$0.338 \pm 0.030$	-0.39
LHCb (2022)	$0.280 \pm 0.018 \pm 0.024$	$0.441 \pm 0.060 \pm 0.066$	-0.43
New average	$0.284 \pm 0.013$	$0.356 \pm 0.029$	-0.37

## Latest status:

**Belle (2019) → no update in 4 years / LHCb run1 (2017) → updated in 2022**

## Waiting lists:

**CMS with “B-parking” / Belle II (first result → in 2023!) / LHCb run2**

# RD(\*): usual interpretations

**NP EFT:**  $\mathcal{L}_X = 2\sqrt{2}G_F V_{cb} C_X^\tau (\bar{c} \Gamma b)(\bar{\tau} \Gamma' \nu)$

## — Solutions to the RD(\*) anomaly

$$C_{VLL}^\tau \approx 0.09$$

$$(\bar{c} \gamma^\mu P_L b)(\bar{\ell} \gamma_\mu P_L \nu)$$

$$C_{VRL}^\tau \approx 0.42i$$

$$(\bar{c} \gamma^\mu P_R b)(\bar{\ell} \gamma_\mu P_L \nu)$$

$$C_T^\tau \approx 0.15 + i 0.19$$

$$(\bar{c} \sigma^{\mu\nu} P_L b)(\bar{\ell} \sigma_{\mu\nu} P_L \nu)$$

$$C_{SLL}^\tau \approx -0.82 + 0.78i$$

$$(\bar{c} P_L b)(\bar{\ell} P_L \nu)$$

**Right-handed neutrino scenarios are skipped here:**

1802.01732, 1804.04135, 1804.04642,  
1807.04753, 1811.04496

## — Models of the mediator particle

**Vector boson (W'):**  $C_{VLL}^\tau, C_{VRL}^\tau$

→ SU(2) model inevitably includes Z' that is very constrained due to tree-level FCNC

**Charged Higgs:**  $C_{SLL}^\tau$

→ typical models (type-I, II) do not give desired SLL and so type-III is the last hope

# RD(\*): usual interpretations

**Leptoquarks (LQ):**  $S_1$ ,  $R_2$ ,  $U_1$

$S_1$  ( $\bar{3}, 1, 1/3$ ) scalar:  $C_{VLL}, C_{SLL} = -4C_T \approx 0.13$

→ VLL & SLL-T type couplings are independent and both has the solution

→ S1-S3 mixture was discussed for RK

1703.09226

$R_2$  ( $3, 2, 7/6$ ) scalar:  $C_{SLL} = +4C_T \approx 0.40 i$

→ could be related to GUT and neutrino mass generation

1701.08322

$U_1$  ( $3, 1, 2/3$ ) vector:  $C_{VLL}, C_{SLL}$

1709.00692, 1808.07492,  
1812.01603, 2103.11889

→ VLL and SLL are independent unless UV is discussed

→ Famous Pati-Salam UV induces  $Z'$  that has to be managed (model dependent)

→ Another UV from  $U(2)$  flavor symmetry gives  $C_{SLL} = -2 e^{I\phi} C_{VLL}$

# Content

- Status on **related observables/measurements** to  $RD(^*)$
- **Impacts** on the NP solutions
  - SM predictions
  - NP in the light lepton modes?
  - Flavor signals:  $B_c$ ,  $\Lambda_b$ , Tau polarizations
  - Collider signals: Tau + missing (+b jet)

# SM predictions (Form Factors)

## BGL parameterization:

+ HFLAV (Spring2019)

## HQET parameterization:

+ EPJC80(2020)74 [3/2/1 model]

+ JHEP08(2020)006 [3/2/1 model]

+ Phys,Rev.D106(2022)096015 [CLN base]

## Why do we have different SM values?:

- FF shape fit is still **unstable** → FF model dependences
- Lattice was available only for **B → D** until last year

## New lattice results for **B → D\*** !!!:

- Fermilab-MILC (2022 published) / HPQCD (2023) / JLQCD (2023)

EPJC 82, 1141 (2022)

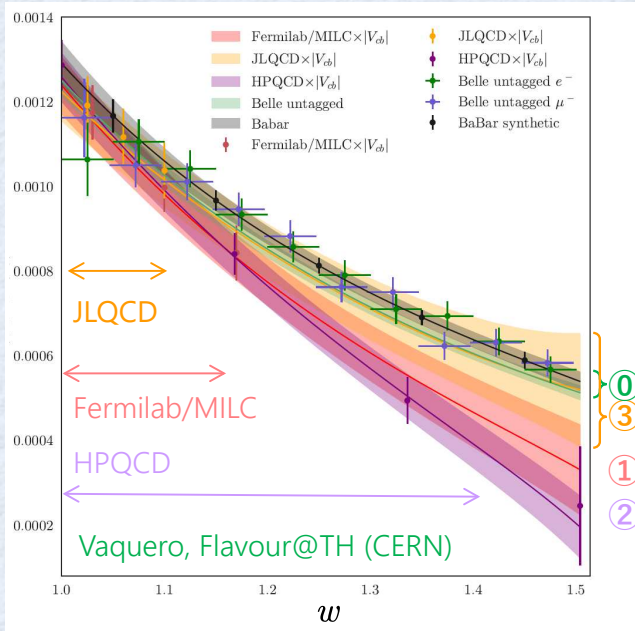

2304.03137

2306.05657

# SM predictions (Form Factors)

New lattice results for  $B \rightarrow D^*$ !!:

— Fermilab-MILC (2022 published) / HPQCD (2022) / JLQCD (2023)

**JLQCD:**

good consistency with exp / small recoil bins

**HPQCD:**

steeper slope / large recoil bins

① extracted from Belle data

③ JLQCD

① Fermilab-MILC

② HPQCD

deviations

**New issue:** how should we combine the lattice results?

**Effect on  $RD^*$ :**

[0.252(22) **JLQCD**] vs [0.279(13) **HPQCD**] vs [0.265(13) **MILC**]

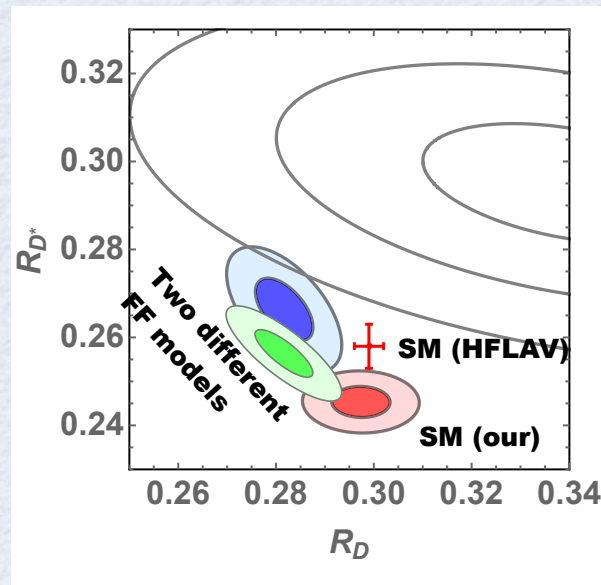

— **JLQCD** consistent with the present status [0.254(5) **HFLAV**]

— **HPQCD & MILC** larger value / reducing the **B** anomaly [0.285(13) **exp**]

# NP in the light lepton modes?

Simultaneous fit of FF + Vcb + NP in  $B \rightarrow D^{(*)} \mu \nu, D^{(*)} e \nu$

2004.10208 (RW)

- assuming LFU type NP in e/μ:  $C_X^e = C_X^\mu$
- taking Belle full angular data (2017,2018) & all available theory
- NP can be hidden behind the Vcb measurement
  - possible size is < 5% of the “SM size”  $\equiv 2\sqrt{2}G_F V_{cb}$
- Impact on  $RD^{(*)}$ , NP in denominator, is mild
  - $RD^*$  increases while  $RD$  decreases in case of VRL type NP

# Flavor signals

## (1) $B_c$ lifetime

**excluded the scalar NP solution (SLL):**

— **Difference in experiment/theory is room for NP contribution** [hep-ph/9601249](#), [1611.06676](#)

$$[\tau_{B_c}^{\text{exp}} \approx 0.5\text{ps}] \text{ vs. } [0.4\text{ps} < \tau_{B_c}^{\text{th}} < 0.7\text{ps}] \Rightarrow \text{Br}(B_c \rightarrow \tau \bar{\nu}) < \frac{30\%}{\tau_{\nu}}$$

→ **killed all the scalar NP solutions to the anomaly**

— **The present calculation (OPE) is sensitive to charm mass input**

→ [1811.09603](#) pointed out a conservative bound should be **< 60%**

→ [2105.02988](#) provides update concerning charm mass: th. could reach **< 1.0ps (< 50%)**

→ **theory calculation is not conclusive, need further update...**

[2201.06565](#)

— **This update significantly affects the SLL scenario**

→ **Scalar type solution revived, but on the edge!**

→ **Type-III charged Higgs is now viable!**

→ **Good news for several LQ scenarios as well**

# Flavor signals

## (2) $\Lambda_b$ decay

Another **R** proposal from b-baryon:  $R_{\Lambda_c} = \mathcal{B}(\Lambda_b \rightarrow \Lambda_c \tau \nu) / \mathcal{B}(\Lambda_b \rightarrow \Lambda_c \ell \nu)$

— light lepton modes were measured by DELPHI/CDF/LHCb since 2004

— the first result for tau together with R was reported by LHCb in this year!

2201.03497

LHCb (2022):  $0.242 \pm 0.026 \pm 0.04 \pm 0.059$   $\Leftrightarrow$  SM (2018):  $0.324 \pm 0.004$

Heavy Quark Symmetry ensures **sum rule**:  $\frac{R_{\Lambda_c}}{R_{\Lambda_c}^{\text{SM}}} = 0.28 \frac{R_D}{R_D^{\text{SM}}} + 0.72 \frac{R_{D^*}}{R_{D^*}^{\text{SM}}} + \delta$

—  $\delta$  can be negligible under any NP existence as long as  $|C_T| \ll 1$

1811.09603, 1905.08253

→ Recall **the T solution**:  $|C_T| \approx |0.15 + i 0.19| = 0.24 \Rightarrow \delta = -0.03$

— measured  $R_{D^*}$  provides **model-independent fit**:  $R_{\Lambda_c}^{\text{fit}} = 0.380 \pm 0.013 \pm 0.005$

→ is **another index** to test the anomaly

→ IOW, this R cannot identify NP but is **a unique value for every NP solution and for SM**

→ the measured  $R_{\Lambda_c}$  is not consistent with the  $R_{D^*}$  anomaly: **potentially another problem**

# Flavor signals

## (3) Tau spin polarization

— NP solutions for RD(\*) anomaly predict distinct signals

→ could identify T/SLL/SRL solution (blue/yellow/cyan)

→ Current experimental measurement

Belle (2017) 1709.00129

**D\* mode:**  $P_{\tau,\text{exp}}^{D*} = -0.38 \pm 0.51^{+0.21}_{-0.16}$

**D mode:** not measured yet

# Collider signals

## W boson resonance:

- has been observed with missing transverse mass
- its **tail** can be interpreted as NP contribution responsible for the  $RD^{(*)}$  anomaly
- minimal NP process is  $bc \rightarrow \tau\nu$ 
  - **W'** is severely constrained:  $< 2\text{TeV}$  excluded (bc PDF suppressed) /  $< 5\text{TeV}$  (SSM)
  - **EFT** based analysis is also available and gives very crucial bound

1811.07920

- competitive with the NP solutions that require large WCs:

$$|C_{VLL}^{\text{LHC-EFT}}| < 0.32 \Leftrightarrow C_{VLL}^{R_{D^{(*)}}} \approx 0.09$$

$$|C_{VRL}^{\text{LHC-EFT}}| < 0.33 \Leftrightarrow C_{VRL}^{R_{D^{(*)}}} \approx 0.42 i$$

$$|C_T^{\text{LHC-EFT}}| < 0.20 \Leftrightarrow |C_T^{R_{D^{(*)}}}| \approx |0.15 + i 0.19| = 0.24$$

$$|C_{SLL}^{\text{LHC-EFT}}| < 0.32 \Leftrightarrow |C_{SLL}^{R_{D^{(*)}}}| \approx |-0.82 + i 0.78| = 1.13$$

- **Charged Higgs** is very excluded, but has an exception

→ tail  $p_T < 500\text{GeV}$  is less sensitive to NP signal

→ mass window  $180\text{GeV} < m_H < 400\text{GeV}$  is not accessible

# Collider signals

## t-channel case:

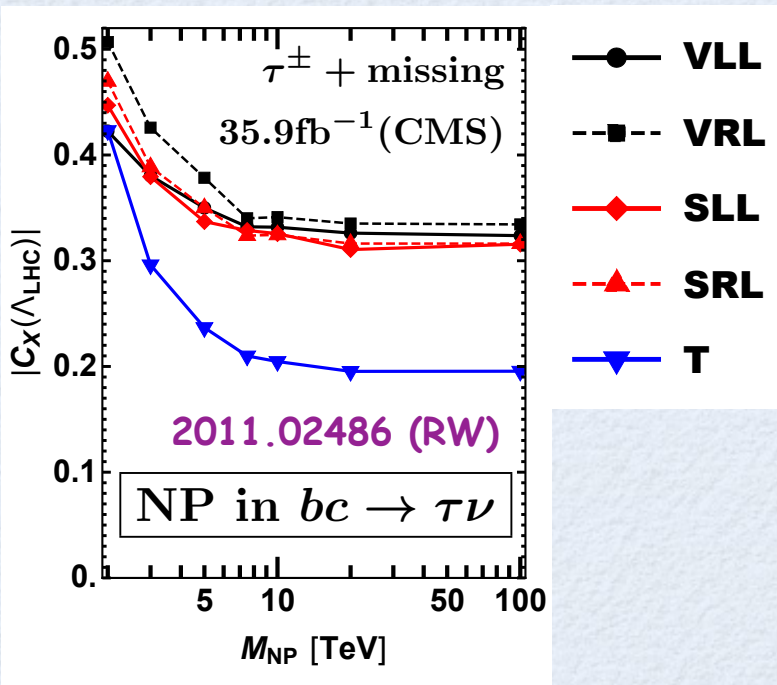

— EFT approximation is not good at high-mT

→ if NP mass is close to **mT bin ~ 1TeV** applicable for bound

→ In particular, it **overestimates** the signal in the case of t-channel

→ Large **t(<0)** generates large mT and **reduces** the contribution

— **ex)**  $\mathcal{L}_U = h_U^{ij} \left( \bar{q}_L^i \gamma^\mu \ell_L^j \right) U_\mu + \text{h.c.} \Rightarrow \frac{h_U^{b\tau} \cdot h_U^{c\nu}}{t - m_{LQ}^2} \neq - \frac{h_U^{b\tau} \cdot h_U^{c\nu}}{m_{LQ}^2} \equiv C_{VLL}$

## Proper bound for t-channel NP:

→ **2TeV LQ**: EFT bound is **40~100%** overestimated

→ **5TeV LQ**: **10~20%** overestimated

→ **T solution is still viable in the case of LQ type**

$$|C_T^{\text{LHC-LQ}}| < 0.42 \Leftrightarrow |C_T^{R_{D^{(*)}}}| \approx |0.15 + i 0.19| = 0.24$$

# Collider signals

## proposal of improvement:

— Requiring **additional b-jet** greatly reduces the SM background 2008.07541

→ comes from  $gq \rightarrow b\ell\nu$  ( $q = u, c$ ) suppressed by  $|V_{qb}|^2$  in the SM

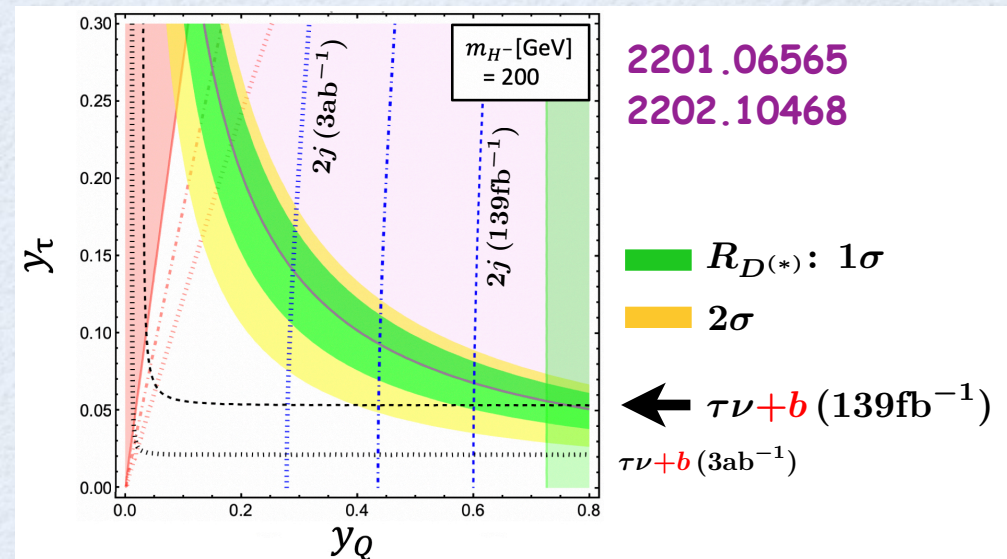

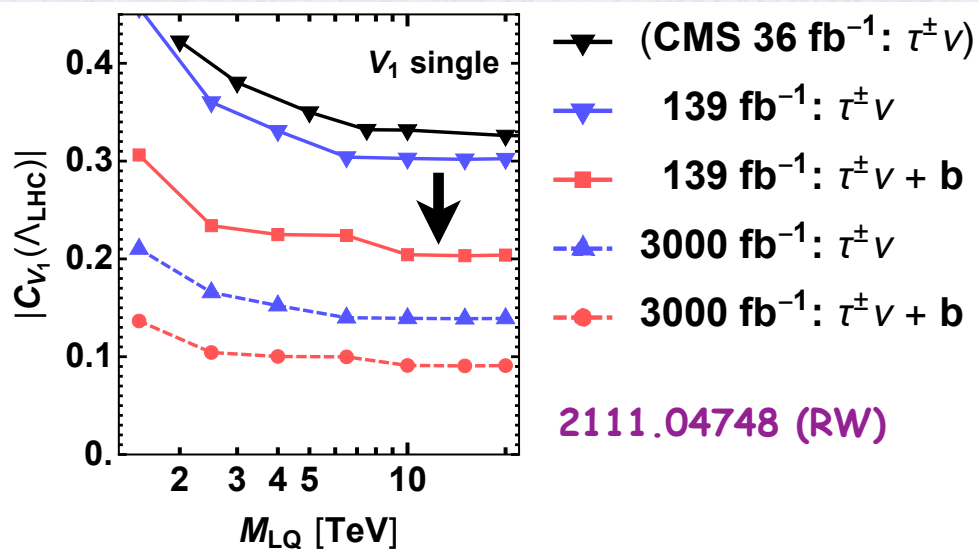

→ simulation shows +b search could improve the LHC bound by **~50%**

→  $3ab^{-1}$  LHC could reach the VLL solution:  $|C_{VLL}^{3ab^{-1}+b}| \lesssim 0.1$

—  $\tau\nu+b$  search can also access  **$m_H < 400\text{GeV}$**  (out of range for  $\tau\nu$  search)

→ suppressing trigger rate could reach up to **180GeV**

→ simulation shows  **$139\text{fb}^{-1}$  data is sufficient** to test the SLL solution for RD(\*)

# Summary

## — SM predictions

- ✓ New **lattice** form factor calculations bring impacts on the SM values

## — NP in the light lepton modes?

- ✓ NP hidden **in the  $V_{cb}$  measurement** is possible ( $< 5\%$ ), but impact on  $RD^{(*)}$  is limited

## — Flavor signals: $B_c$ , $\Lambda_b$ , Tau polarizations

- ✓  $B_c \rightarrow \tau \nu$  has great **potential to pin down** the  $RD^{(*)}$  solution → **CEPC** has a crucial role!
- ✓  $R_{\Lambda c}$  has model-independent **sum rule with  $RD^{(*)}$** , and gives **another index** for the anomaly

## — Collider signals: Tau + missing (+ b jet)

- ✓ **High- $p_T$  ( $>500\text{GeV}$ ) tail** is sensitive to NP responsible for  $RD^{(*)}$ , and **already competitive**
- ✓ EFT bounds already excluded some  $RD^{(*)}$  solutions, while **t-channel bounds more milder**
- ✓ **Additional b-jet tag** will improve the collider bound and **reach 10% precision**

**Backup**

# Lattice results competition

Vaquero [WG1+2] Tue 18:03

Colquhoun [WG2+3] Thu 18:50

## tension on $B \rightarrow D^* \ell \nu$

$$|\eta_{EW} V_{cb} \mathcal{F}|^2 \mathcal{F}^2 \propto \left[ 2 \frac{1 - 2wr + r^2}{(1 - r)^2} \left\{ 1 + \frac{w - 1}{w + 1} R_1^2 \right\} + \left\{ 1 + \frac{w - 1}{1 - r} (1 - R_2) \right\}^2 \right] h_{A_1}^2 \quad R_1 = \frac{h_V}{h_{A_1}}, \quad R_2 = \frac{h_{A_3} + r h_{A_2}}{h_{A_1}}$$

### ① Belle and BaBar data

#### ① Fermilab/MILC : steeper slope ?

+  $\chi^2/\text{dof} \sim 1.5$  to fit w/ exp data

#### ② HPQCD : even steeper slope !

+ significant tension with exp ( $\ell=e, \mu$ ) at medium/large  $w$   
+  $|V_{cb}| = 44.2(1.8) \times 10^{-3}$  from total  $\Gamma$

#### ③ JLQCD : good consistency w/ exp

① – tension on  $R_2$  (?) [Belle 2301.07529, Jung Flavour@TH]

② – small recoils [JLQCD, Fermilab/MILC]  $\Leftrightarrow$  larger  $ap$  [HPQCD]

$\Rightarrow$  “safe” extension to large  $w$ : JLQCD; Fermilab/MILC  $a^{-1} \sim 6.6 \text{ GeV}$

# Flavor signals

## (2) $B_c$ decay

The “**R**” observable for  $B_c$ :  $R_{J/\psi} = \mathcal{B}(B_c \rightarrow J/\psi \tau \nu) / \mathcal{B}(B_c \rightarrow J/\psi \mu \nu)$

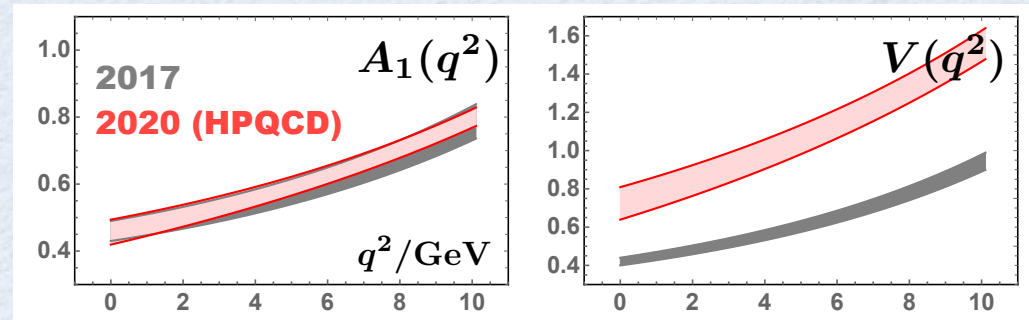

1711.05623

LHCb (2017):  $0.71 \pm 0.17 \pm 0.18$   $\Leftrightarrow$   
35%

SM (2017):  $0.28 \pm 0.05$  1709.08644  
 SM (2019):  $0.24 \pm 0.01$  1901.08368  
 SM (2022):  $0.258 \pm 0.004$  2204.04357

- Update is planned in the LHCb roadmap
  - error could go into **8% in 5 years**
- Sufficiently crucial for the  $RD^*$  anomaly
  - NP prediction on  $R_{J\psi}$  can be tested

- FF updated: 2007.06957
  - QCD (2017)/ SR (2019) / lattice (2020)
  - deviations affected the SM value

- NP prediction from the  $RD^*$  solution:
  - ex) VLL solution predicts **0.28-0.29**
  - Summary given later

# NP in the light lepton modes?

## (1) Simultaneous fit of FF + Vcb + NP in $B \rightarrow D^{(*)} \mu \nu, D^{(*)} e \nu$

2004.10208 (RW)

- assuming LFU type NP in e/ $\mu$   $C_X^e = C_X^\mu$
- taking Belle full angular data (2017,2018) & all available theory
  - processes usually used to measure Vcb
- NP can be hidden behind the Vcb measurement
  - possible size is < 5% of the “SM size”  $\equiv 2\sqrt{2}G_F V_{cb}$
- Impact on  $RD^{(*)}$ , NP in denominator, is mild
  - $RD^*$  increases while  $RD$  decreases in case of VRL type NP

## (2) New anomaly in angular obs. $\Delta A_{FB} = A_{FB}(D^* \mu \nu) - A_{FB}(D^* e \nu)$

2104.02094, 2203.07189

- using Belle 2018 data, angular asymmetries can be constructed
- “anomaly” was observed in the FB asymmetry between e/ $\mu$ 
  - Single NP operators difficult / Tuned NP couplings needed
  - Impact on  $RD^{(*)}$  is very limited since  $Br(e/\mu) = 1 \pm 0.01$

# Result 1/2

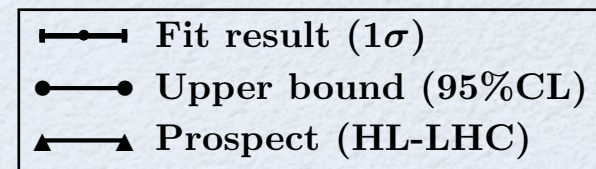

## Mediator (LQ) mass dependence:

### (WC definition)

●	V1	$2\sqrt{2}G_F V_{cb} [C_{V_1}(\bar{c}\gamma^\mu P_L b)(\bar{\ell}\gamma_\mu P_L \nu)$
■	V2	$+C_{V_2}(\bar{c}\gamma^\mu P_R b)(\bar{\ell}\gamma_\mu P_L \nu)$
◆	S1	$+C_{S_1}(\bar{c}P_R b)(\bar{\ell}P_L \nu)$
▲	S2	$+C_{S_2}(\bar{c}P_L b)(\bar{\ell}P_L \nu)$
▼	T	$+C_T(\bar{c}\sigma^{\mu\nu} P_L b)(\bar{\ell}\sigma_{\mu\nu} P_L \nu)]$

## Impact on Flavor (Vcb+NP fit):

# Result 2/2

## The tau case:

**EFT)**  $|C_T|_{\text{LHC}} < 0.20$  (95%CL)

**LQ)**  $|C_T|_{\text{LHC}} < 0.42$  (95%CL)

$$\leftrightarrow |C_T|_{R_{D^{(*)}}} \approx |0.15 + i 0.19| = 0.24$$

### (Summary)

**2TeV LQ:** EFT bound is **40~100% overestimated**

**5TeV LQ:** **10~20% overestimated**

## Impact on Flavor ( $R_{D^{(*)}}$ ) anomaly:

# + b-jet tag

2111.104748

— Requiring **additional b-jet** greatly reduces the SM background

$$\ell^\pm \nu + b \Big|_{\text{SM}} \Rightarrow gq \rightarrow b\ell\nu \quad (q = u, c) \Rightarrow |V_{ub,cb}|^2 \text{ suppression}$$

**Improvement ①: stronger bound is simply expected**

— can look into detail of the **U1-LQ** model = SM-like vector operator

$$\mathcal{L}_U = h_U^{ij} \left( \bar{q}_L^i \gamma^\mu \ell_L^j \right) U_\mu + \text{h.c.} \quad C_{V_1} \equiv -\frac{h_U^{b\tau} \cdot h_U^{c\nu}}{m_{\text{LQ}}^2}, \text{ but indeed } h_U^{c\nu} = h_U^{s\ell}$$

$$\ell^\pm \nu \Big|_{U_1\text{-LQ}} \Rightarrow cb, cs \rightarrow \ell\nu \Rightarrow \text{The } C_{V_1} \text{ bound is valid only if } h_U^{b\tau} \gg h_U^{c\nu} \text{ for } U_1\text{-LQ}$$

$$\ell^\pm \nu + b \Big|_{U_1\text{-LQ}} \Rightarrow cg \rightarrow b\ell\nu \Rightarrow \text{no } s \text{ quark, (but could be mis-tagged)}$$

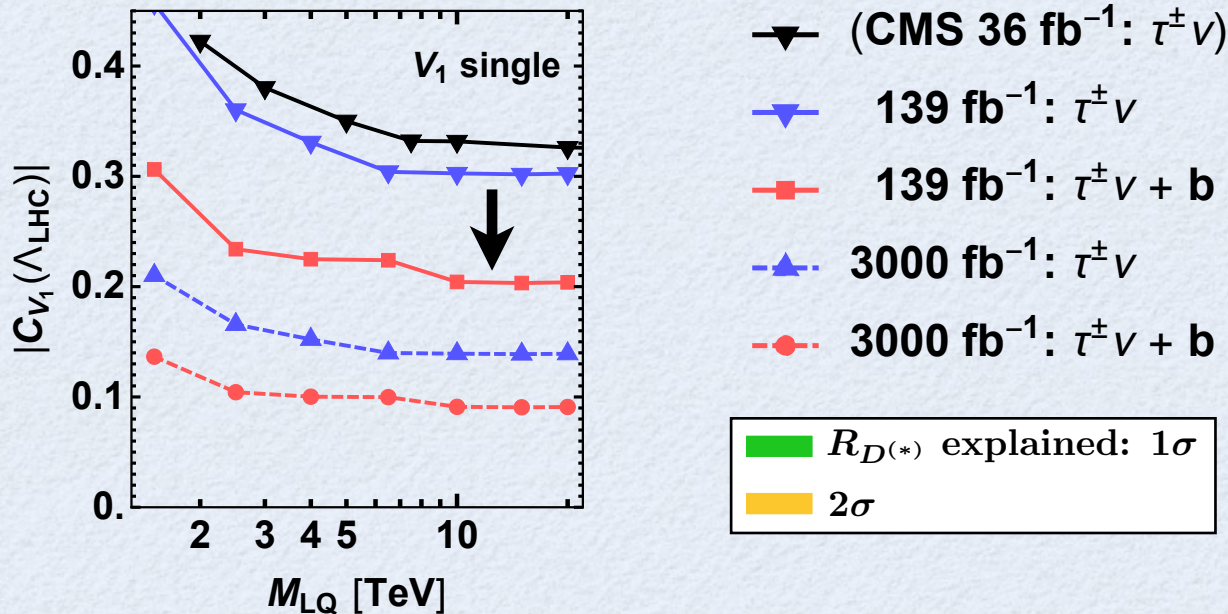

**Improvement ②: complementary bound on the two couplings**

# + b-jet tag

2111.104748

(BG/Signal events generated & simulated: details skipped)

Improvement ①:

Improvement ②:

Observations:

- +b search improves the bound by **~50%**
- +b search at HL\_LHC can achieve  **$Cx \sim 0.1$** , i.e. **10% NP effect**
- Given the LQ mass, the two couplings (**not combination**) are constrained

# FF parameterization

## CLN

Caprini, Lellouch, Neubert (1997)

- “**Traditional**” parameterization based on HQET
- Form Factors are **approximated** and **related with each other**

**Cons:** parameterization is valid only up to  $1/m_Q$  correction

Comparison: inclusive decay has no  $(1/m_Q)^1$  but starts from  $(1/m_Q)^2$

## BGL

Boyd, Grinstein, Lebed (1997)

- “**General**” parameterization with minimum requirement
- Each Form Factor involves **independent parameters**

**Cons:** FFs in New Physics involve new unknown parameters

# FF parameterization

## ✓ “general HQET”

[Jung, Straub \(2018\)](#), [Bordone, Jung, Dyk \(2019\)](#)

— **general HQET based** parameterization

— includes higher order corrections **at the cost of larger parameter set**

**Pros:** NNLO could be competitive to NLO because  $(\Lambda/m_c)^2 \sim (\Lambda/m_b)^1$

**Pros:** Including NNLO is also a fair comparison with inclusive mode

## ✓ Modeling

HQET property: **one LO / three NLO / six NNLO** Isgur-Wise functions

Parameterization: ex)  $\xi(w) \equiv \sum_{n=0}^{N_{\text{LO}}} a_{\xi}^{(n)} z^n$       **Truncation order:** arbitrary

Two proposed modelings for the truncation orders:

\* CLN is naively (3/0/-)

$$(N_{\text{LO}}/N_{\text{NLO}}/N_{\text{NNLO}}) = \begin{cases} (3/2/1) & \rightarrow \mathbf{23 \text{ parameters!}} \\ (2/1/0) & \rightarrow \mathbf{13 \text{ parameters!}} \end{cases}$$

# Tau Polarization in LQ
