

# SeaQuest and SpinQuest Experiment: Fixed-target Drell-Yan Program at Fermilab

Kun Liu

Los Alamos National Laboratory

12<sup>th</sup> Workshop on Hadron Physics and Opportunities Worldwide

August 7, 2024

Managed by Triad National Security, LLC, for the U.S. Department of Energy's NNSA.

# Outline

- Introduction to physics motivation
- SeaQuest results
- SpinQuest status
- Summary and future prospects

# Intro to Physics Motivation

## The inner structure of proton

Other than charge, valence quarks only contribute to part of the proton's properties: *mass, momentum, spin*

### Investigation(s) of the proton structure

- QCD
- Lattice QCD
- Experimental probs:
  - Deep Inelastic Scattering
  - Drell-Yan - *focus of our Fermilab experiments*

### Describing quarks inside the proton

- Parton model
- Parton distribution function  $f(x)$
- Structure functions

$$F_2^p(x) = \sum_i x Q_i^2 f_i(x)$$

# Intro to Physics Motivation

## Looking into the light quark sea

- Proton as a sum of quarks:

$$P = \underbrace{q_u^1 + q_u^2 + q_d^3}_{\text{Valence}} + \underbrace{\sum_i q_{sea}^i \bar{q}_{sea}^i}_{\text{Sea}}$$

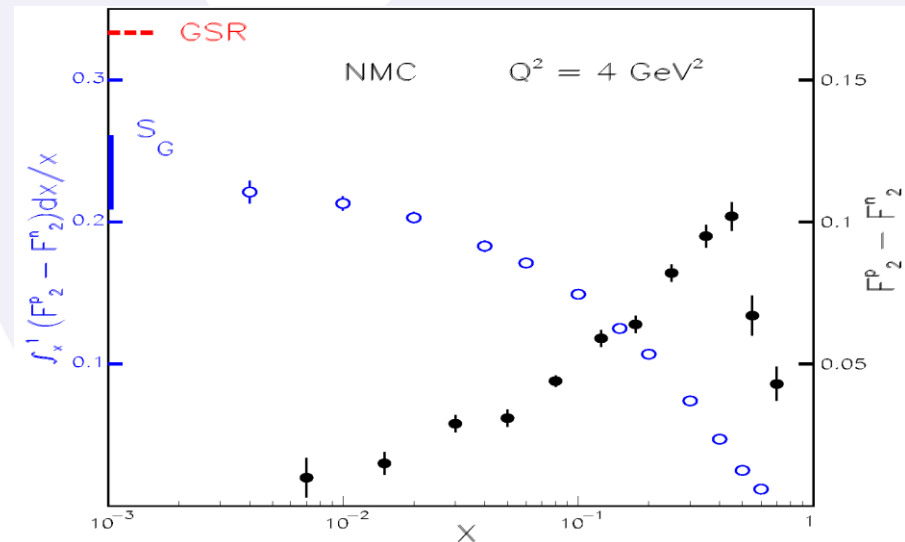

- Separate the sea from the valence

$$\int_0^1 [F_2^p(x) - F_2^n(x)] \frac{dx}{x} = \frac{1}{3} - \frac{2}{3} \int_0^1 [\bar{d}_p(x) - \bar{u}_p(x)] dx$$

**Gottfried Sum Rule**

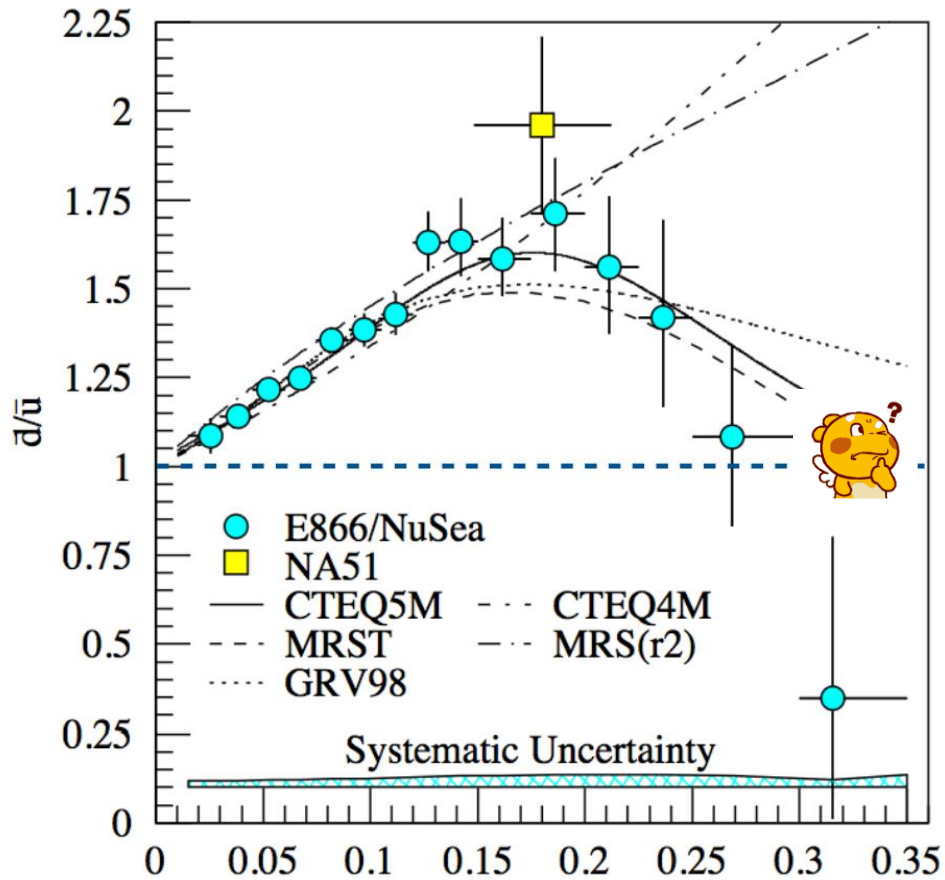

- NMC tested the Gottfried Sum Rule by muon DIS on hydrogen and deuterium

$$\int_0^1 [F_2^p(x) - F_2^n(x)] \frac{dx}{x} = 0.235 \pm 0.026$$

# Intro to Physics Motivation

## Sea quark flavor asymmetry

*All models introduce a  $\bar{d}$  excess, however the data beyond  $x \sim 0.3$  is hard to be incorporated*

- Assuming charge symmetry, ignoring the nuclear effects and heavy quark contributions:

$$\left. \frac{\sigma^{pd}}{2\sigma^{pp}} \right|_{x_1 \gg x_2} \approx \frac{1}{2} \left[ 1 + \frac{\bar{d}(x_2)}{\bar{u}(x_2)} \right]$$

- NA51 and NuSea/E866 revealed a striking asymmetry of the anti-quarks at moderate  $x$
- Many models proposed to explain the anti-matter asymmetry:

- Meson cloud
- Pauli blocking
- Chiral quark model
- Instantons
- Statistical parton distributions
- ...

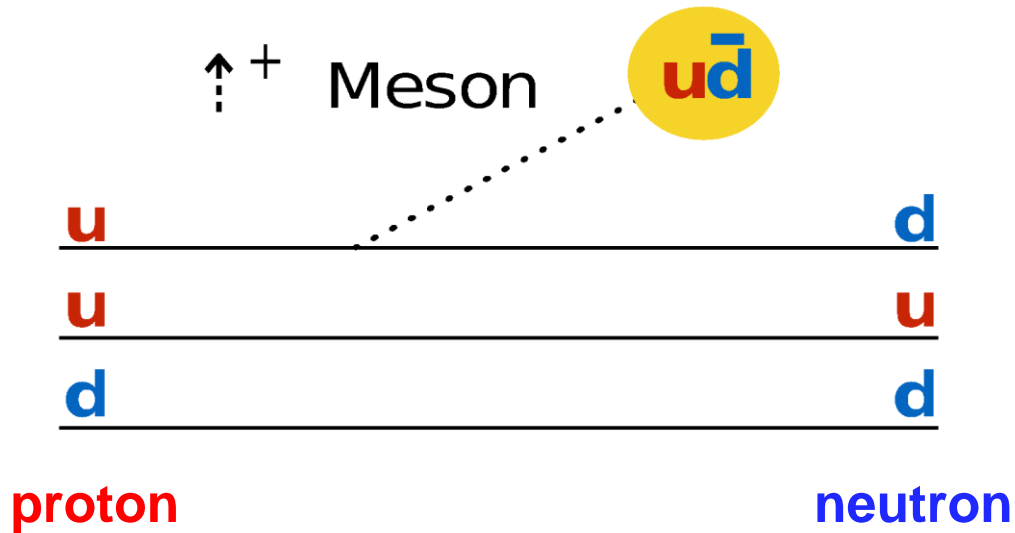

# Intro to Physics Motivation

## Sea-quark's orbital motion

### Pion cloud model

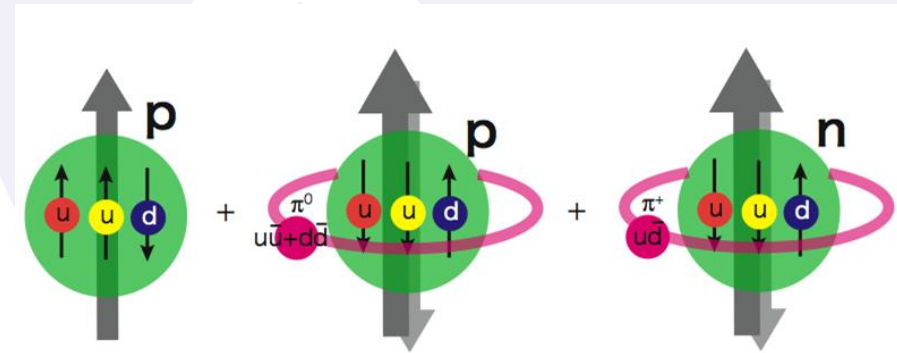

- Sea-quark flavor asymmetry
- Sea-quark orbital angular motion
- Expect large Sivers function at  $x = 0.1 - 0.4$

### Pion cloud and Drell-Yan process

$$|p\rangle = a_1|p_0\rangle + a_2|p_0 + \pi^0\rangle + a_3|n + \pi^+\rangle + \dots$$

# Intro to Physics Motivation

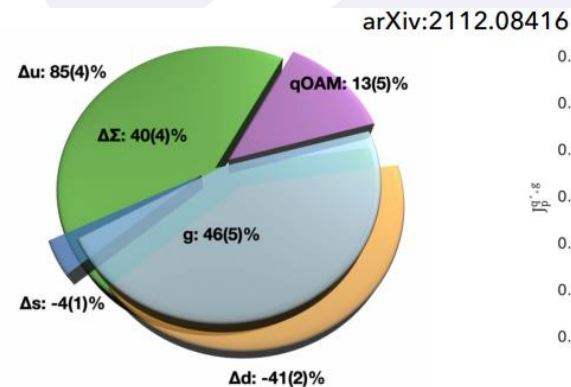

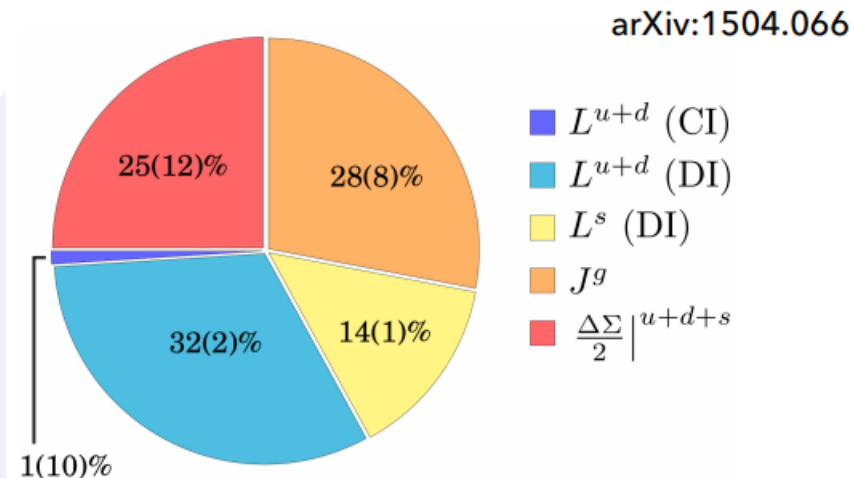

## Proton spin puzzle/crisis and sea-quark OAM

$$\Delta\Sigma \sim 0.25 \pm \dots$$

$$\int_{0.05}^{0.2} dx \Delta g(x) = 0.2 \pm 0.06$$

50% comes from OAM: 38 - 46 (20) % gluons  
13 - 18 (50) % quarks

■ sea  
■ valence

# Intro to Physics Motivation

## Probe the proton spin through TMDs and Sivers function

TMD = Transverse Momentum Dependent PDF

|                                 |   | quark          |                |                |
|---------------------------------|---|----------------|----------------|----------------|
|                                 |   | Unpol.         | Long.          | Trans.         |
| n<br>u<br>c<br>l<br>e<br>o<br>n | U | $f_1$          |                | $h_1^\perp$    |
|                                 | L |                | $g_1$          | $h_{1L}^\perp$ |
|                                 | T | $f_{1T}^\perp$ | $g_{1T}^\perp$ | $h_1^\perp$    |

The quark Sivers distribution (function)

The Sivers function vanishes if the quarks have no **orbital motion**

Anselmino, M. et. all, [https://doi.org/10.1007/JHEP04\(2017\)046](https://doi.org/10.1007/JHEP04(2017)046)

Simultaneous measurement of both ubar and dbar  
 Statistics shown for 2 calendar years of running

# SeaQuest/SpinQuest Experiment at Fermilab

## E906/SeaQuest: 2012 – 2017

- 120 GeV proton beam with unpolarized proton/deuteron, and nuclear targets

## E1039/SpinQuest: 2018 – now

- 120 GeV proton beam with polarized proton/deuteron target

# SeaQuest/SpinQuest Experiment Setup

NM3: looking downstream

NM4: looking upstream

cryo platform

shielding

collimator

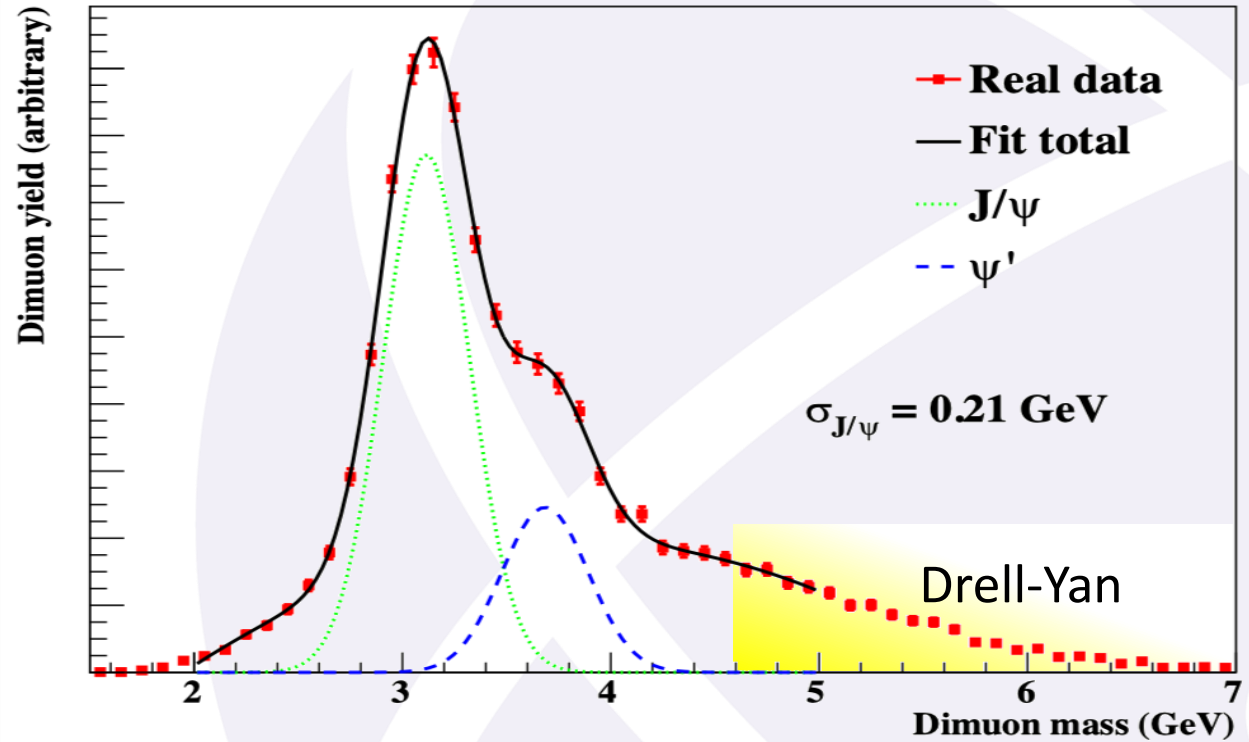

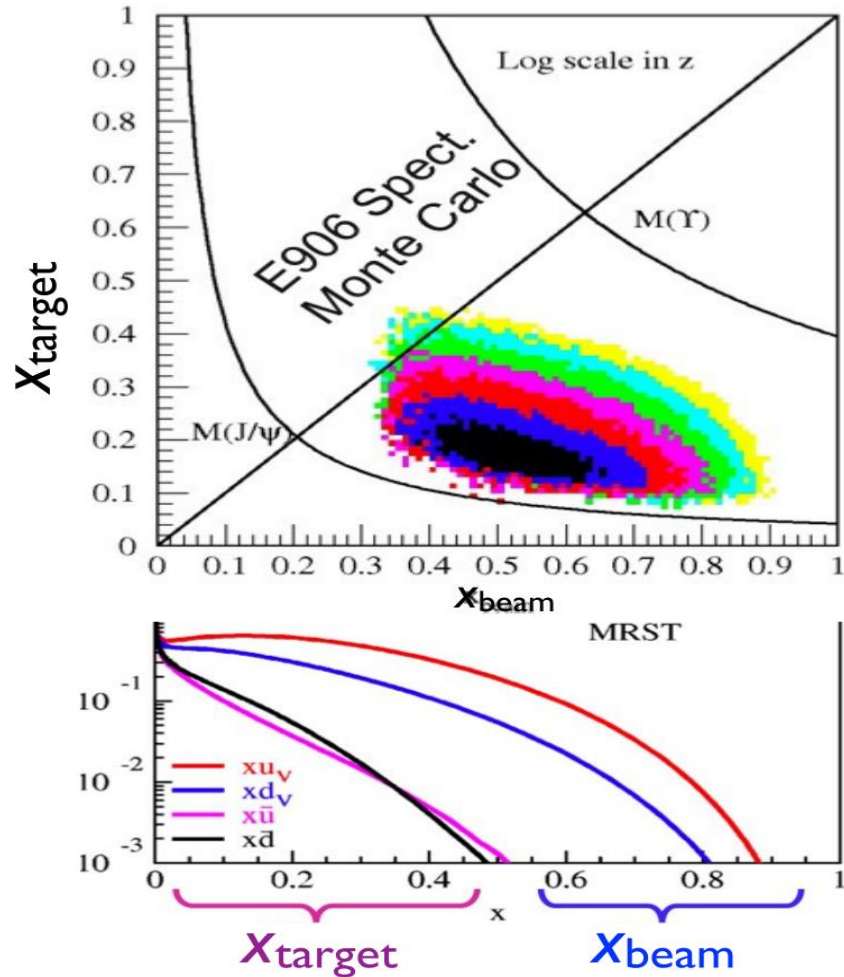

target cave

spectrometer

beam direction

# SeaQuest Results

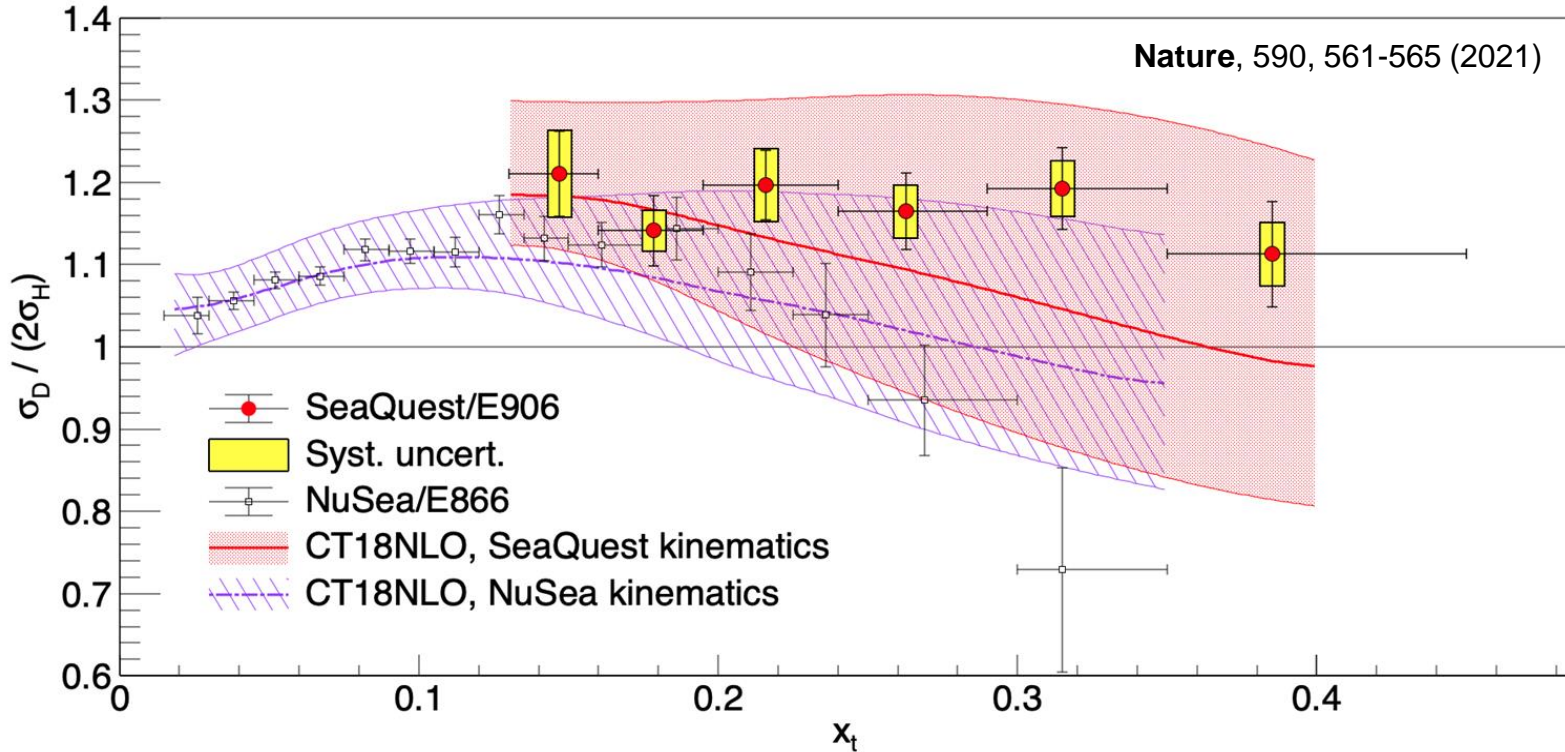

## Typical mass spectrum and kinematic coverage

$$\frac{d^2\sigma}{dx_b dx_t} = \frac{4\pi\alpha^2}{9x_b x_t s} \sum_q e_q^2 [\bar{q}_t(x_t)q_b(x_b) + \cancel{q_t(x_t)\bar{q}_b(x_b)}]_{\text{small}}$$

# SeaQuest Results

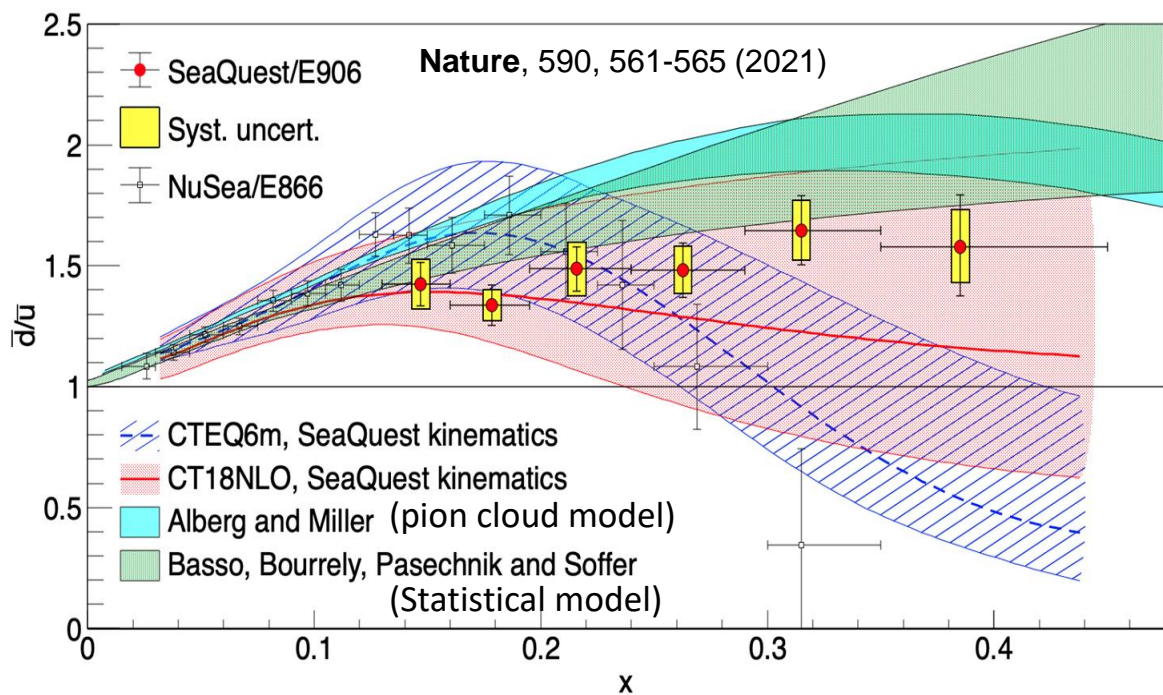

## Drell-Yan cross-section ratio

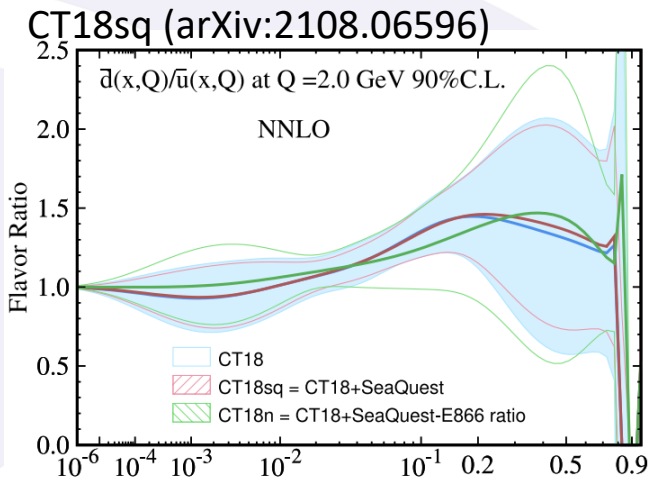

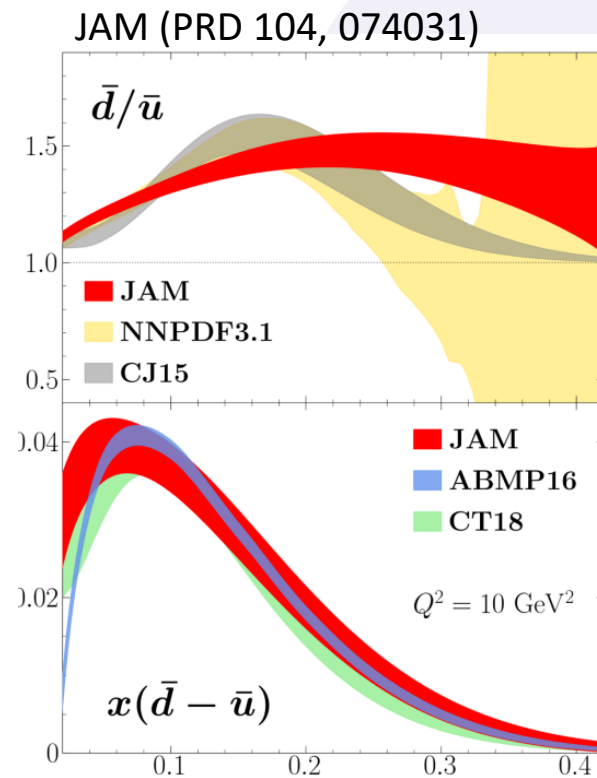

- SeaQuest results compared with E866/NuSea data shows discrepancy at higher  $x$
- Effects of experimental kinematics (120 GeV vs. 800 GeV beam) has been studied
  - Shown by the calculation using CT18 NLO
  - Account for the difference at  $x \sim 0.15$

# SeaQuest Results

## Sea-quark flavor asymmetry

- Reasonably described by two theoretical predictions
- Included in multiple global analysis
- Improved analysis with more data is ongoing

# Other SeaQuest Results

## $J/\psi$ and $\psi(2s)$ cross section

- NRQCD with NNPDF4.0 described the data pretty well
- At SeaQuest energy ( $\sqrt{s} = 15$  GeV), both  $J/\psi$  and  $\psi(2s)$  have sizable  $q\bar{q}$  contributions and are sensitive to the sea quark flavor asymmetry

arXiv:2406.11459, submitted to PLB

# Other SeaQuest Results

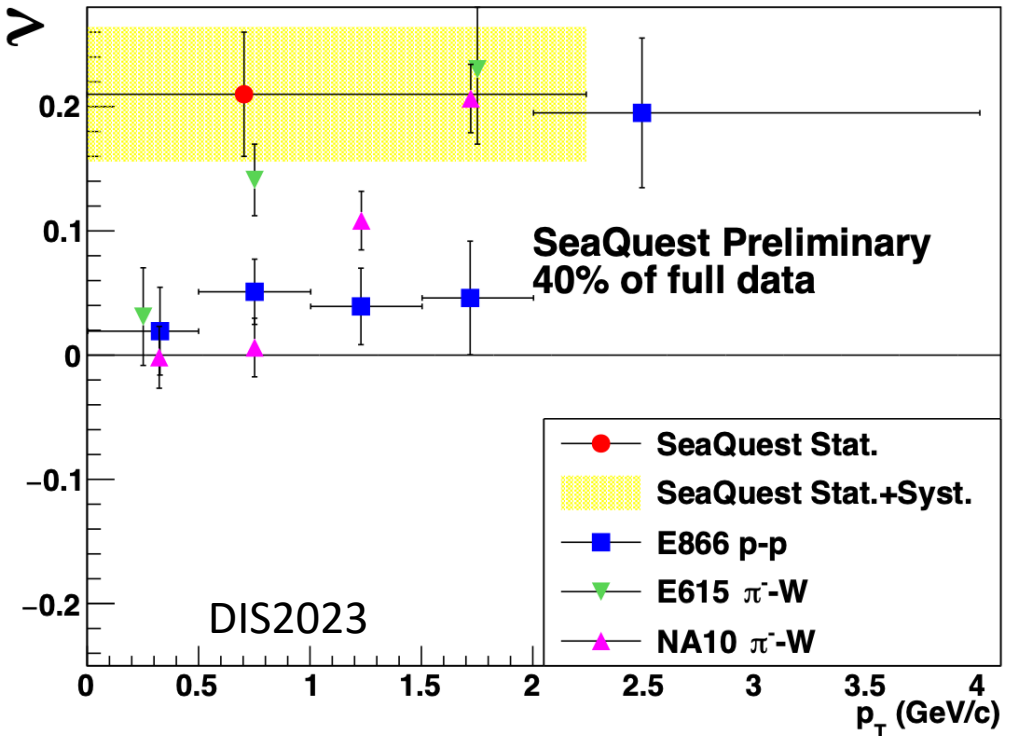

## Extraction of Boer-Mulders function

- Drell–Yan angular distribution is essential to access Boer–Mulders function:

$$d\sigma/d\Omega \propto 1 + \lambda \cos^2\theta + \mu \sin 2\theta \cos\phi + \frac{\nu}{2} \sin^2\theta \cos 2\phi,$$

$$\nu/2 \propto h_{1,\text{beam}}^\perp h_{1,\text{target}}^\perp, \text{ where } h_1^\perp \text{ is Boer–Mulders function } \gg$$

- A large  $\nu$  value was obtained
  - ❑ Similar to  $\pi$ -induced Drell–Yan results
  - ❑ We may need to re-consider an assumption that the Boer–Mulders functions of sea-quarks are small
- Preliminary result presented at DIS2023, paper draft under preparation

# Other SeaQuest Results

## Initial-state energy loss in cold nuclear medium

I. Vitev et al

Nuclei targets:

p+p, p+d, p+C, p+Fe and p+W

Nuclear modification factor:

$$R_{pA} = \frac{2\sigma^{pA}}{A \times \sigma^{pD}}$$

$$x_F = \frac{P_{DY}}{P_{beam}}$$

# SpinQuest Status

## Transition from SeaQuest to SpinQuest

- ① Beam Collimator
- ② Target Shielding
- ③ ROOTS Vacuum Pump
- ④ Helium Liquefier
- ⑤ Beam Dump/FMag
- ⑥ Station-1 Hodoscope & Tracking
- ⑦ KMag
- ⑧ Station-2 hodoscope & tracking
- ⑨ Station-3 Hodoscope & Tracking
- ⑩ Absorber
- ⑪ Station-4 Hodoscope & Muon Identification

### Inherited from SeaQuest (5 – 11)

- A beam/spectrometer combination with well-understood capabilities and limitations
- Necessary instrumentation to cope with high instantaneous intensity environment
- Well-established analysis procedure

### New polarized target system (1 – 4)

- Tighter beam requirements (better shielding and new collimator)
- Cryogenic infrastructure (liquefier, pump, service platforms, etc.)
- Larger operation and maintenance overhead
- Additional systematic uncertainties

# SpinQuest Status

## Polarized target

- Refurbished from a longitudinal polarized target used at SLAC and rotated the magnet to be a transversely polarized target
- Dynamic Nuclear Polarization process to get nucleon polarization

### Key specs

- Material: frozen beads of  $\text{NH}_3/\text{ND}_3$  (7.9 cm long caps)
- 5T vertical superconducting magnet ( $<10^{-4}$  homogeneity)
- High cooling capacity 1K  $^4\text{He}$  evaporation refrigerator
- High power microwave system
- 3 NMR coils per cup
- $>90\%$  polarization for proton and  $>40\%$  polarization for deuteron

**Unparalleled high luminosity and polarization**

# SpinQuest Status

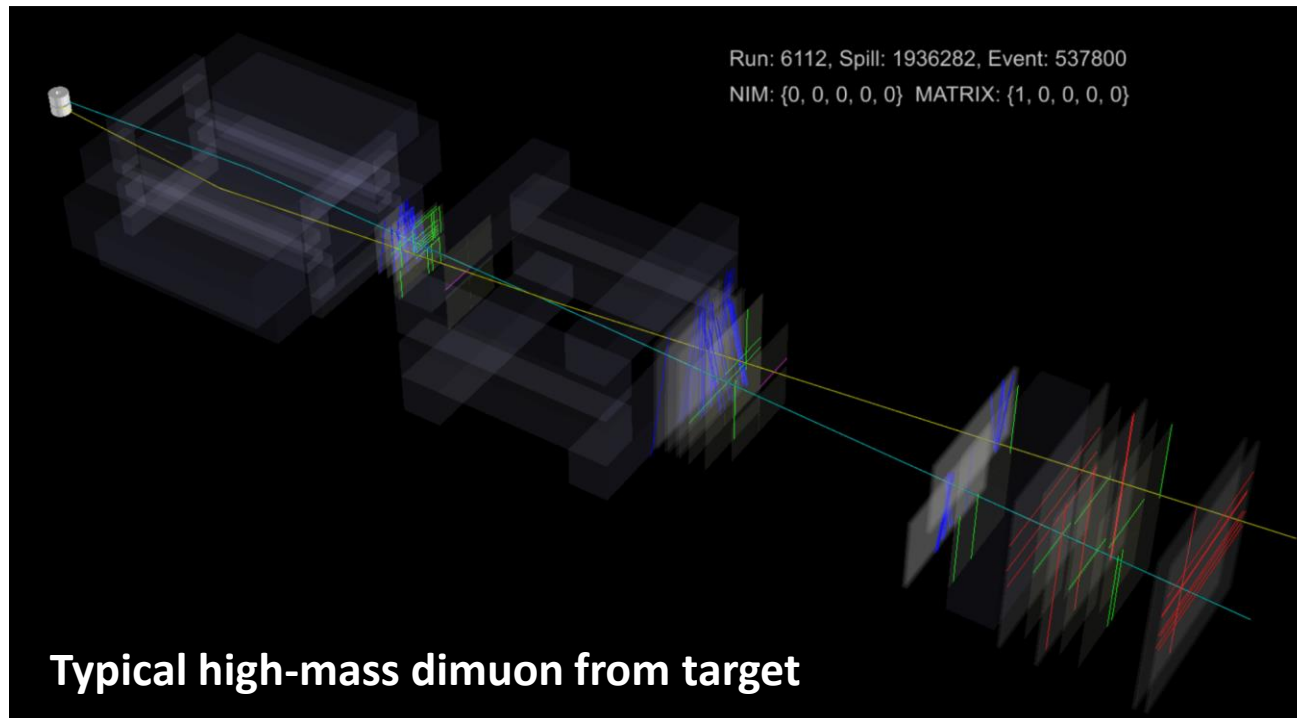

## Polarized target successfully tested with beam

- After many years of installation and delays, we finally took the first commissioning and short production run in June
- Successful operation of polarized target in high-intensity proton beam up to  $3E12$  protons per pulse
- Reached 26% polarization with  $CH_2$  target
- Reached 90% polarization with  $NH_3$  target

# SpinQuest Status

## First short production run

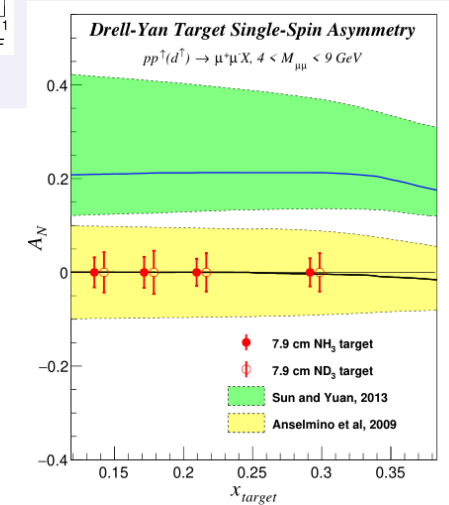

### Online reconstruction

- The first short production run with  $4E15$  protons on polarized target – roughly a few hundred  $J/\psi$  events are expected for the first peek on the  $J/\psi$  TSSA measurement
- Clear  $J/\psi$  and high-mass dimuon events (dominated by beam dump events) observed in the online plots
- Offline analysis of the production data is ongoing

# Summary and Future Prospects

- Very rich QCD dynamics and sea-quark distributions inside the proton
- **Anti-quark flavor asymmetry remains large at intermediate  $x$ , no sign of getting smaller as indicated in the previous statistics-limited data**
  - ❑ Excludes some early proton models
- SpinQuest started data-taking this summer, with two years of production data taking planned
  - ❑ Expect first determination of sea-quark Sivers functions, probing OAM from sea-quarks
  - ❑ Shed new light on the proton structure, spin puzzle, and potentially constrains the future EIC nucleon structure physics program
  - ❑ **Now is the time to join us!**

VOLUME 25, NUMBER 5      PHYSICAL REVIEW LETTERS      3 AUGUST 1970

## MASSIVE LEPTON-PAIR PRODUCTION IN HADRON-HADRON COLLISIONS AT HIGH ENERGIES\*

Sidney D. Drell and Tung-Mow Yan

Stanford Linear Accelerator Center, Stanford University, Stanford, California 94305  
 (Received 25 May 1970)

On the basis of a parton model studied earlier we consider the production process of large-mass lepton pairs from hadron-hadron inelastic collisions in the limiting region,  $s \rightarrow \infty$ ,  $Q^2/s$  finite,  $Q^2$  and  $s$  being the squared invariant masses of the lepton pair and the two initial hadrons, respectively. General scaling properties and connections with deep inelastic electron scattering are discussed. In particular, a rapidly decreasing cross section as  $Q^2/s \rightarrow 1$  is predicted as a consequence of the observed rapid falloff of the inelastic scattering structure function  $\nu W_2$  near threshold.

# Unique sensitivity to sea-quarks

The Drell-Yan Process:

$$\frac{d^2\sigma}{dx_b dx_t} = \frac{4\pi\alpha^2}{9x_b x_t} \frac{1}{s} \sum_q e_q^2 [\bar{q}_t(x_t)q_b(x_b) + \cancel{q_t(x_t)\bar{q}_b(x_b)}]$$

small

**Unique sensitivity to sea quarks!**

# Tracking software challenges for SeaQuest

Huge variations in the instantaneous beam intensity  $\longrightarrow$  high hit rate/detector occupancy

- This is the first time extracting beam from Fermilab Main Injector, duty factor initially  $< 10\%$ 
  - high intensity (super) buckets saturates the detector
  - completely kills DAQ
  - huge background poses serious challenge to reconstruction
- Partial solution: bucket-by-bucket beam intensity monitor
  - inhibit trigger at super bucket just to keep DAQ alive
  - measure the proton lost due to DAQ busy
- *Christmas miracle* (in 2014): turning on one forgotten switch significantly improves the duty factor

# Angular Distribution for Drell-Yan

- Collins–Soper frame
  - ▶ Virtual photon rest frame
  - ▶  $\theta$ : polar angle of positive lepton
  - ▶  $\phi$ : azimuthal angle of positive lepton

- Drell–Yan cross section

$$\frac{d\sigma}{d\Omega} \propto 1 + \lambda \cos^2 \theta + \mu \sin 2\theta \cos \phi + \frac{\nu}{2} \sin^2 \theta \cos 2\phi$$

- ▶ Naively,  $\lambda = 1$ ,  $\mu = \nu = 0$  ( $d\sigma \propto 1 + \cos^2 \theta$ ) at leading order
  - ★ No transverse momentum on quarks
  - ★ No gluon emission
- ▶ NLO:  $\lambda \neq 1$ ,  $\mu, \nu \neq 0$ , but  $\lambda$  and  $\nu$  still satisfy  $1 - \lambda = 2\nu$   
 (**Lam–Tung relation**)
- Lam–Tung relation
  - ▶ Analogue of Callan–Gross relation (scattering of spin 1/2 particles)
  - ▶ Satisfied when the quark-antiquark axis is coplanar to hadron plane

# Dynamic Nuclear Polarization

Given the small magnetic moment of the proton we can not reach a significant polarization just by using a large B field and a low T.

$$P = \tanh\left(\frac{\mu B}{kT}\right)$$

- Proton has small magnetic moment

$$\mu_e \approx 660\mu_p$$

- At B = 5 Tesla & T = 1 K

$$P_e = \sim 98\%, P_p = 0.51\%$$

- Dynamic Nuclear Polarization

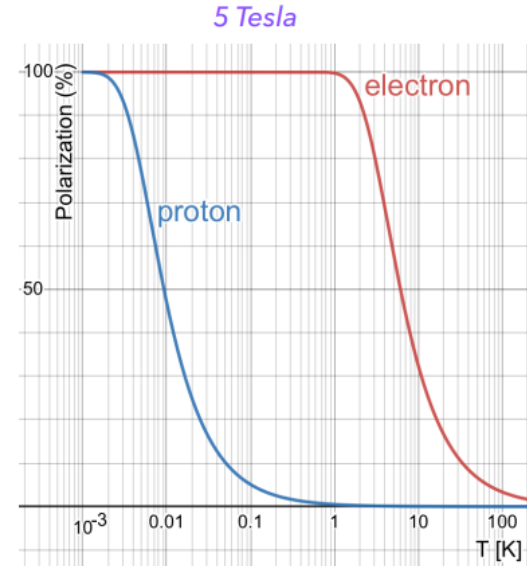

- Dope target material with paramagnetic centers:

chemical or irradiation doping to just the right density ( $10^{19}$  spins/cm<sup>3</sup>)

- Polarize the centers: Just stick it in a magnetic field

- Use microwaves to transfer this polarization to nuclei:

mutual electron-proton spin flips re-arrange the nuclear Zeeman populations to favor one spin state over the other

The disparity in relaxation times between the electron (ms) and proton (tens of minutes) at 1K is crucial to continue proton polarization.

Allows to achieve proton polarization of > 90%

# SpinQuest Collaboration

- 22 institutions from 7 countries (Armenia, China, India, Sri Lanka, Pakistan, Japan, USA)
- 50 active collaborators
  - ❑ 13 grad students
  - ❑ 7 postdocs
  - ❑ 30 faculties
- 18 collaborators reside in or near Fermilab

# Fermilab accelerator schedule

# Importance of sea-quarks in the proton spin

## Recent lattice QCD results

K.-F. Liu *et al* arXiv:1203.6388

$$DS_q \gg 25\%$$

$$L_u \approx -L_d$$

$$2L_q \gg 46\% \quad (0\%(\text{valence})+46\%(\text{sea}))$$

$$2J_g \gg 25\% \quad J_g = DG + L_g$$

**Orbital angular momentum ? Sea quarks' angular momentum could be a major part of the "missing spin".**

- All of the quark orbital momentum comes from the sea quark contribution
- Important to understand it experimentally and theoretically

# TMDs – Sivers function

## Quark distribution functions

|                                 |   | quark          |                |                         |
|---------------------------------|---|----------------|----------------|-------------------------|
|                                 |   | Unpol.         | Long.          | Trans.                  |
| n<br>u<br>c<br>l<br>e<br>o<br>n | U | $f_1$          |                | $h_1^\perp$             |
|                                 | L |                | $g_1$          | $h_{1L}^\perp$          |
|                                 | T | $f_{1T}^\perp$ | $g_{1T}^\perp$ | $h_1$<br>$h_{1T}^\perp$ |

The quark Sivers distribution (function)

$$f_{1T}^{\perp[C]}(x, k_T^2) (\vec{S}_T \cdot \vec{k}_T) = \frac{M}{2} \text{F.T.} \langle P, S_T | \bar{\psi}(0) \mathcal{L}_C(0, \xi) \not{k}_- \psi(\xi) | P, S_T \rangle |_{\xi^+ = 0}$$

The Sivers function vanishes if the quarks have no **orbital motion**

Expected dramatic increase at lower x

- Focus on transverse momentum – 3D structure of the nucleon

# Sivers asymmetry in polarized Drell-Yna

Left-right asymmetry in Drell-Yan di-muon production on a polarized nucleon

Cornerstone prediction of QCD factorization

$$f_{1T}^{\perp q} |_{SIDIS} = -f_{1T}^{\perp q} |_{DY}$$

$$SIDIS = - DY$$

- The same quark Sivers distribution in both processes, but with **an opposite sign**

Deeply rooted in the **gauge invariance in QCD**

**DOE Milestone:** "Test unique QCD predictions for relations between single-spin phenomena in **p-p scattering** and those observed in deep-inelastic scattering"

# SpinQuest Expected Results and Impact

*Simultaneous measurement of both ubar and dbar  
 Statistics shown for 2 calendar years of running*

$$A_N^{DY} \propto \frac{u(x_b) \cdot f_{1T}^{\perp, \bar{u}}(x_t)}{u(x_b) \cdot \bar{u}(x_t)}$$

Existing data do not put enough constraints on the sea quark Sivvers distribution, neither sign nor value

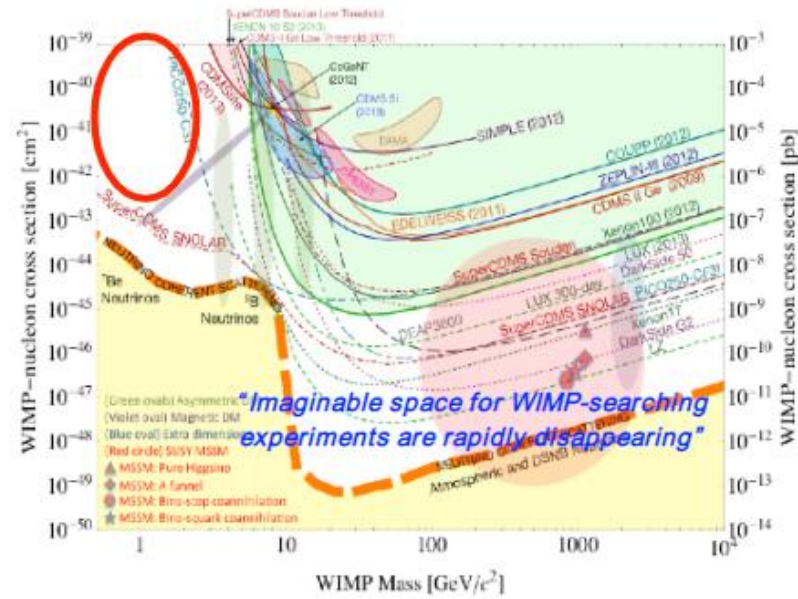

## If $A_N \neq 0$ , major discovery:

- “Smoking gun” evidence for  $L_{\text{sea}} \neq 0$
- Determine sign and value for sea quark Sivvers function
- Confirm global analysis expectations

## If $A_N = 0$ :

- $L_{\text{sea}} = 0$ , spin puzzle more dramatic?
- Sea quark flavor asymmetry hard to explain

# Dark Sector Physics Extension

# Understanding Jet quenching at RHIC/LHC

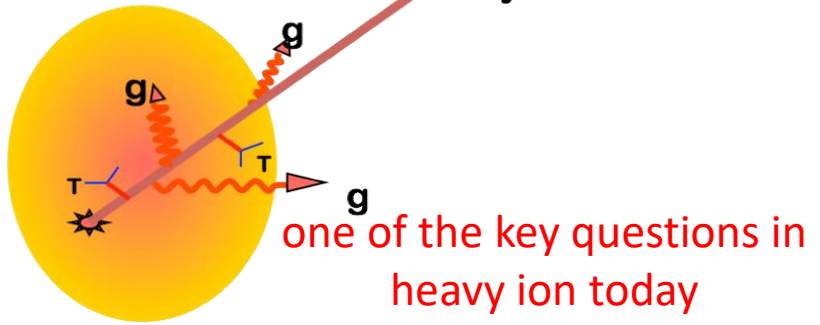

Energy loss of partons from hard scattering through re-scattering in the hot and dense medium (Quark Gluon Plasma)

- nuclear modification factor  $R_{AA} \ll 1$  at high  $p_T$

$$R_{AA} = \frac{\text{Yield}_{AA}}{\langle N_{\text{binary}} \rangle_{AA} \text{Yield}_{pp}} \sim 1 - \int \rho \otimes \frac{dE}{dx}$$

## Single Hadron Tomography

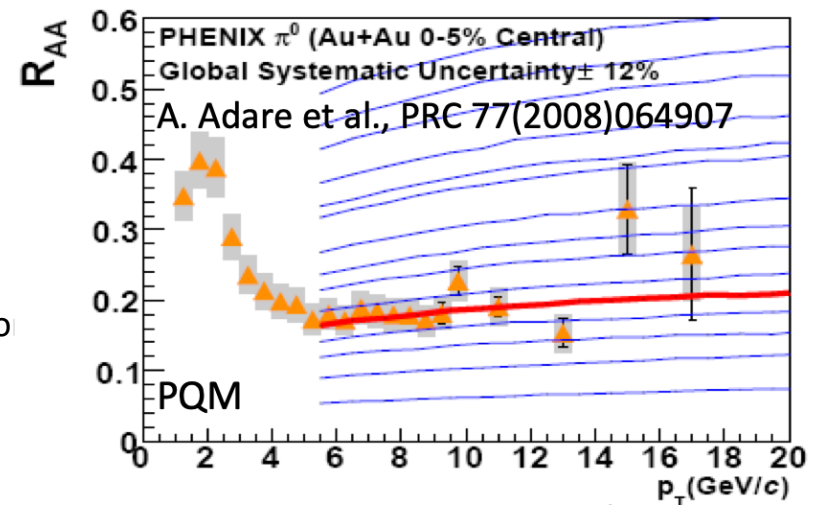

Recent JET collaboration progress (PRC 90, 014909 (2014)) for 10 GeV quark:

- $\hat{q} = 1.2 \pm 0.3 \text{ GeV}^2/\text{fm}$  for RHIC
- $\hat{q} = 1.9 \pm 0.7 \text{ GeV}^2/\text{fm}$  for LHC

Access medium properties through statistical analysis:

- example: transport coefficient
- model dependent**

**Measurement of Cold Nuclear Medium will help pin down the model uncertainty**

# Dark Sector Expected Results

First data taking parasitically with SpinQuest/E1039: FY24 – FY25
