## The Tagged Neutron Method or Associated Particle Technique

H. H. BARSCHALL, I. ROSEN, R. F. TASCHEK, J. H. WILLIAMS, Rev. Mod. Phys., V. 24, 1 (1952):  
Since neutrons arise only from nuclear reactions, there always exist at the time of their formation one or more charged particles associated with each neutron. In some cases a one-to-one correspondence exists between neutron and charged particle, and the counting of these charged particles with known efficiency determines the associated neutron flux.

NEUTRON SOURCE INCORPORATING A  
SOLID STATE ALPHA-PARTICLE  
DETECTOR, Nucl. Instr. Meth., pp.49-52,  
Jan.-Feb. 1963.

## Development and Applications of the Tagged Neutron Method at JINR

At the end of 1990<sup>th</sup> **V.M.Bystritsky** and **M.G.Sapozhnikov** proposed to study the tagged neutron method using the Van de Graaff EG-5 electrostatic accelerator at FLNP. The first experiments were started in 1999.

The first installation had a tritium target of 1.7 curie, a single-channel alpha detector based on ZnS and a gamma detector made of a NaI(Tl) crystal with a diameter of 200 mm.

An important stage in the development of the TNM was the creation of a portable neutron generator, which was carried out by the N.L. Dukhov All-Russian Research Institute of Automatics, Moscow (**VNIIA**) in 2003, according to the technical specifications developed at JINR.

~5 m

~30 cm

### Main characteristics:

|                        |                                    |
|------------------------|------------------------------------|
| Maximal intensity      | $\sim 5 \cdot 10^7 \text{ c}^{-1}$ |
| Neutron energy         | 14.1 MeV                           |
| Neutron radiation mode | steady-state                       |
| Operation time         | $\sim 800$ hours                   |

# The Tagged Neutron Method with ING-27 compact neutron generators

The 14.1 MeV neutron is tagged in time and direction by detecting the associated  $\alpha$ -particle released in the opposite direction.

Main advantages of the method:

- significantly reduced background
- direct measurement of the neutron flux
- position sensitivity
- possibility to select time-correlated events using coincidences

## Application of the TNM: detection of hazardous substances

**DVIN-1** is a portable system designed for detecting concealed explosives in inspected objects. The **DVIN-1** analyzes the elemental composition of substances and can identify over **30 explosive materials**. The key advantage of **DVIN-1** over gas analyzers is its ability not only to detect the possible presence of explosives but also to **pinpoint their exact location** within the inspected object.

# Application of the TNM: elemental composition of minerals

Decomposition of  
the spectrum from  
dolomite  
( $\text{CaCO}_3 \cdot \text{MgCO}_3$ )

Mass fraction of oxides according to chemical analysis and as a result of fit procedure.

|            | $\text{SiO}_2$ | $\text{MgO}$  | $\text{FeO}$   | $\text{Al}_2\text{O}_3$ | $\text{CaO}$   | $\text{CO}_2$  |

# Application of the TNM: Search for large diamonds in kimberlite ore

Fig. 24. General schematic view of the pilot separator.

- Kimberlite ore is irradiated by 14.1 neutrons from the neutron generator.
- Characteristic  $\gamma$ -ray spectra are measured by the BGO detectors and analyzed separately for each ING-27 voxel.
- The condition for finding the diamond is a local excess of the count rate for gamma-rays with energies  $\sim 4.43$  MeV (characteristic line of carbon)

| Energies | Counts | Integration PM |       |       |       |       |

## Design of an ore separator

- Separator productivity 1060 kg/h.
- Minimum diamond size 8 mm.
- False detection probability 3%.

# TNM with high resolution gamma spectrometry

- energy spectrum in the coincidence window
- random background in the same coincidence window
- Pure spectrum after background subtraction

## Developing and optimizing signal processing techniques for the TANGRA project experimental setups

How?

See report of P. Kharlamov at ISINN-31

Side view

View from above

Setup for measurement of differential cross sections of  $\gamma$ -ray emission. Includes 2 HPGe and 4 LaBr<sub>3</sub> detectors. The geometry is optimized using Geant4.

**See report of D. Grozdanov at ISINN-31**

Diagram energy ( $E_\gamma$ ) – the time between the registration of a  $\gamma$ -quantum and its corresponding  $\alpha$ -particle ( $T_\gamma - T_\alpha$ ) formed as a result of reactions in the sample, with a highlighted coincidence window.

Example of time spectra (in the energy window of about 1 – 2 MeV) for HPGe detector a) and LaBr detector b).

Where: A – With sample, B – Without sample, C – Difference.  
1 – is  $\gamma$ -from (Fe – Pb) - Collimator, 2 –  $\gamma$  from sample, 3 – is scattered neutrons

**See report of D. Grozdanov at ISINN-31**

## Determination of the efficiency of the detector system. Analysis of chlorine neutron capture experiment for efficiency calculation validation

See report of C. Hramco at ISINN-31

## Measurement of differential cross sections of neutron scattering on $^{12}\text{C}$

Scheme of the experimental setup with plastic detectors for measuring angular distributions of the scattered neutrons. 1 – ING-27 neutron generator, 2 – irradiated carbon sample, 3 – one of the 20 plastic detectors used in the registration system.

Neutron source: ING-27 generator

Sample: graphite block, 44 cm x 44 cm x 2 cm

Neutron detectors: polyphenyltoluene scintillators

## Measurement of differential cross sections of neutron scattering on $^{12}\text{C}$

Examples of the time-of-flight spectra obtained. Peaks are labelled with source reaction, registered particle is painted red.

A – is measurement with target ( $^{12}\text{C}$ ), Time  $\sim 48\text{h}$ ;

B – is measurement without target (Background), Time  $\sim 28\text{h}$ ,

C – Net spectra (without background)

$(n, X\gamma_0)$  –  $\gamma$  from ING-27

$(n, X\gamma_1)$  –  $\gamma$  from target ( $^{12}\text{C}$ )

$(n, X\gamma_2)$  –  $\gamma$  from the opposite wall

$(n, n_0)$  - elastic scattering

$(n, n_1)$  - inelastic scattering to the 1 excited state of  $^{12}\text{C}$  4.44MeV

$(n, n_2)$  - inelastic scattering to the 2 excited state of  $^{12}\text{C}$  7.65MeV

$(n, n_3)$  - inelastic scattering to the 3 excited state of  $^{12}\text{C}$  9.64MeV

$(n, n_4)$  - inelastic scattering to the 4 excited state of  $^{12}\text{C}$  10.30MeV

$(n, n_5)$  - inelastic scattering to the 5 excited state of  $^{12}\text{C}$  10.84MeV

## Characterization of an EJ-200 plastic scintillator array for experiments with 14-MeV tagged neutrons

The experimental setup consisting of 20 plastic EJ-200 scintillators

The measured efficiency values vs the GEANT4 simulation

The measured light output function for protons in comparison with other datasets

- The new approach based on the tagged neutron method has been implemented to characterization of the organic scintillator based detectors. It was based on scattering of neutrons on carbon and hydrogen nuclei.
- The light output functions for protons and  $\alpha$ -particles were measured
- The detection efficiency was experimentally measured relative to the the standard of the cross section of the elastic scattering of neutrons on hydrogen
- The results obtained has been used to calculate the cross section in the experiments on investigation of the neutron emission

**See report of P. Prusachenko at ISINN-31**

# Experimental and theoretical study of $(n-n'-\gamma)$ angular correlations

- 10 long (1 m) plastic scintillator detectors with 2 PMT made by EPIC CRYSTALL
- Detectors are placed at angles from  $15^\circ$  to  $135^\circ$  with step  $30^\circ$
- 2 long detectors are placed above and below the target

**$(n', \gamma)$  correlations are important for:**

- Understanding the reaction mechanism
- Testing the theoretical predictions
- Checking for nuclear forces invariance for  $n$  and  $p$

**See report of P. Filonchik at ISINN-31**

# Investigation of triple (n-n'-γ) correlations: theoretical description

Differential probability of gamma-quanta emission dependence on inelastic scattered neutron direction

$$dw(\vec{n}_\beta, \vec{n}_\gamma) = A \sum_{Q=0,2,4,\dots,\Lambda\Lambda'} \sum_{\Lambda\Lambda'} D_{\Lambda'Q}^\Lambda \phi_{\Lambda'Q}^\Lambda(\vec{n}_k, \vec{n}_\beta, \vec{n}_\gamma) d\Omega_\beta d\Omega_\gamma$$

$$A = \frac{\omega a_L(e)^2}{2\hbar c^3 k_\alpha k_\beta r_\beta^2} \frac{m_\beta}{m_\alpha},$$

$$D_{\Lambda'Q}^\Lambda = \sqrt{2Q+1} C_{L1Q0}^{L1} U(I_f I_i L Q, L I_i) \sqrt{(2I_i+1)(2\Lambda'+1)} \times$$

$$\sum_{JJ'} g_{J'} \sum_{l_\alpha l'_\alpha j_\alpha j'_\alpha l_\beta l'_\beta j_\beta j'_\beta} \boxed{S_J(l_\alpha j_\alpha \rightarrow l_\beta j_\beta) S_{J'}(l'_\alpha j'_\alpha \rightarrow l'_\beta j'_\beta)} \sqrt{(2J+1)(2j'_\beta+1)} \times$$

$$C_{l'_\alpha 0 \Lambda 0}^{l_\alpha 0} C_{l'_\beta 0 \Lambda' 0}^{l_\beta 0} U(s j'_\alpha l_\alpha \Lambda, l'_\alpha j_\alpha) U(I_\alpha J' j_\alpha \Lambda, j'_\alpha J) U(s j'_\beta l_\beta \Lambda', l'_\beta j_\beta) \begin{Bmatrix} J & j_\beta & I_i \\ J' & j'_\beta & I_i \\ \Lambda & \Lambda' & Q \end{Bmatrix}.$$

S-matrix coefficients from TALYS

FIG 2. Angular distribution of  $\gamma$  radiation for  $^{12}\text{C}$  and  $^{28}\text{Si}$

See poster of A. Andreev at ISINN-31

# Determination of carbon concentration in soil using the tagged neutron method

BGO detectors

distribution of reactions by depth

Carbon concentration is determined by the amplitude of the characteristic 4.44 MeV gamma-line.

## NAS: Neutron Analyzer of Soil

# Conclusions

The tagged neutron method (TNM) is an effective tool for studying the reactions of fast neutrons with nuclei, which makes it possible to successfully implement a program for measuring differential cross sections of neutron scattering and  $\gamma$ -ray production, as well as a program for the application of the TNM for non-destructive elemental analysis.
