Distribution of experimental results by radiation cross sections of gamma quanta with an energy of 4439 keV in the reaction $^{12}\text{C}(n,n'\gamma)^{12}\text{C}^*$;

The discrepancy is two times!!!

Nowadays, the most complete collection of data on reaction cross sections (n,n'γ) for neutrons with an energy of 14.5 MeV is presented in INDC(CCP)-413 (*Status of experimental and evaluated discrete γ-ray production at E_n=14.5 MeV* 1998 r.

Evaluation of the $^{48}\text{Ti}(n,n'\gamma_{984\text{keV}})$ γ -ray production cross section for standards

Tagged neutron method

Experimental setup

Drawing of ING-27: 1 – neutron generator target, 2 – α -detector (256pixel), 3 – signal connector of α -detector, 4 – high-voltage power connectors, 5 - low-voltage control connector

Drawing of LaBr₃(Ce) γ -detector: 1 — the LaBr₃(Ce) crystal, 2 — aluminum case of the detector, 3 — magnetic shielding, 4 — Hamamatsu R10233 PMT tube. Dimensions in the outline drawing are in mm.

Experimental setup

A setup for measuring cross sections and angular distributions of gamma rays in (n,n' γ) reactions.

1- ING-27, 2 – Sample, 3 - LaBr₃(Ce) detectors. All dimensions are in mm.

Sample chracteristic

Sample	Density (g/cm ³)	Size (cm ³)	Isotopic composition
SiO ₂	2.47	44 x 44 x 1.9	²⁸ Si – 92.2%, ²⁹ Si – 4.7%, ³⁰ Si – 3.1% ¹⁶ O – 98.7%, ¹⁷ O – 0.04%, ¹⁸ O – 0.25%
Al	2.70	44 x 44 x 0.7	²⁷ Al – 100%
Ti	4.34	44 x 44 x 0.9	⁴⁶ Ti – 8.25%, ⁴⁷ Ti – 7.44%, ⁴⁸ Ti – 73.72%, ⁴⁹ Ti – 5.41%, ⁵⁰ Ti – 5.18%,
Fe	7.87	44 x 44 x 0.9	⁵⁴ Fe – 5.84%, ⁵⁶ Fe – 91.75%, ⁵⁷ Fe – 2.11%, ⁵⁸ Fe – 0.28

Measurement of “tagged” neutron beam profiles

2D-detector, made of 4 double-sided stripped position-sensitive Si-detectors

Each Si detector consists of 32 x 32 strips ~1.8 mm thick
Size of one detector: 60x60 mm²

Total size: 120x120 mm²

Thickness: 0.3 mm

Neutron detection efficiency:
~ 0.8%

Data processing methodology. Time spectra

Examples of the time-of-flight spectra obtained.
Peaks are labelled with source reaction.

We identified two main sources of the background in our spectra.

a: Random coincidence (2). b: $(n, X\gamma_0)$ - γ from ING-27 (4)

Where: 1 – Full sample energy spectra, 3 – Sample–Random,

6 – Net spectra (without background from ING27).

And 6 is peak form sample 92 (keV) from $^{27}\text{Al}(n, \alpha)^{24}\text{Na}$.

Data processing methodology. Energy spectra

Where:
1 – HPGe detector,
2 – LaBr₃(Ce) detector.
The position of γ -peaks identified by TalysLib.

Data processing methodology. Calculation of cross sections

Area of γ -peak

Incident angle

Total reaction cross section

$$\frac{d\sigma}{d\Omega}(\theta) = \frac{N_p \cos \xi}{4\pi N_\alpha n_{at} k} 10^{27} \left[\frac{\text{mbarns}}{\text{sr}} \right]$$

Number of tagged neutrons

Surface density of atoms in the sample

$$\sigma = 2\pi \int_{-1}^1 \frac{d\sigma}{d\Omega}(\cos\theta) d\cos\theta$$

Multiple inelastic scattering

Attenuation of incident neutron

Sample thickness

Attenuation of γ -rays

- The features of the experimental approach are the close geometry and the quite large sample
- All corrections changed significantly depending on the target thickness
- We could not consider the various correction independently

$$k = \int_0^{x_0} \varepsilon(x) k_{ms}(x) k_{satt}(x) k_{iatt}(x) dx$$

The total efficiency

Algorithm for determining the correction factor

There are two ways to calculate corrections:

- To calculate them independently in dependence on the sample thickness and take the integral
- **To simulate the total thickness-integrated correction in the GEANT4 using a separate ones as weighting factors**

Correction features:

- Multiple inelastic scattering overstates the number of emitted γ -rays
- Attenuation of incident neutrons and γ -rays understates the number of emitted γ -rays

Simulation features:

- 2 stage - neutron transport and γ -rays transport simulation
- The inelastic multiple scattering is used as a probability factor increasing the number of emitted γ -rays in comparison with its real number
- The inelastic multiple scattering correction calculates taking into account the energy dependence of emission cross section for specific γ -line taken from TALYS for each interaction point
- The correction factor resulted included thickness-integrated multiple scattering, absorption and efficiency coefficients

Simulation of the interaction point and neutron spectra depending on thickness

Calculation of the inelastic multiple scattering correction depending on the thickness

Simulation of γ -rays detection efficiency emitting them from the interaction points

Example of the multiple scattering correction

Multiple scattering correction factor depending on the sample thickness. The example corresponding to the SiO_2 sample and first vertical strip

Integrated correction factors using the example of the SiO_2 sample

The correction factors including the attenuation correction, total efficiency and multiple inelastic scattering corresponding to the various $\text{LaBr}_3(\text{Ce})$ detectors

Conclusion

As a result of the experiment, the applicability of the discussed installation for measuring cross sections and angular distributions was demonstrated.

The data obtained demonstrate satisfactory agreement with the results of the most recent measurements performed by other authors.

For the first time, we measured the cross sections of 170, 280 keV lines from Oxygen. And from Aluminum 90, 792, 896, 955, 1129, 1506, 1720, 2298. And from Silicon 1623, 2217, 4497. And from Titanium 121, 130, 175, 370, 1037, 2633. Also from Iron 125, 212, 314, 367, 377.

Thanks for your attention!
