Application of NeatIBP: Two-loop-five-point diagrams in phenomenology processes

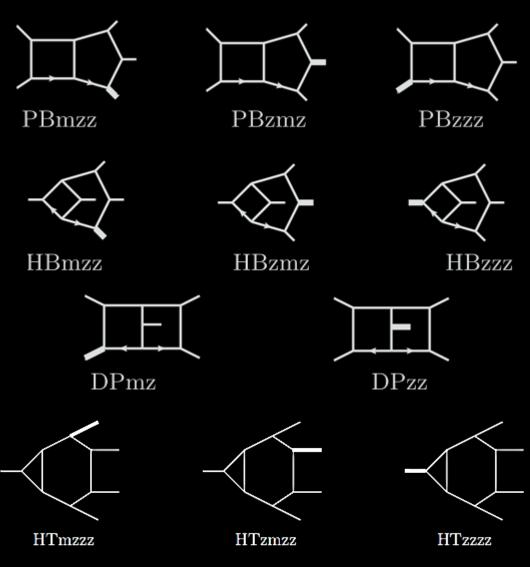

Simon Badger, Heribertus Bayu Hartanto, ZW, Yang Zhang and Simone Zoia, JHEP 03 (2025) 066

Simon Badger, Heribertus Bayu Hartanto, Rene Poncelet, ZW, Yang Zhang and Simone Zoia, *JHEP* 12 (2025) 221

Relevant Feynman diagrams

NeatIBP generated IBP relations within hours for each diagram

JHEP 03 (2025) 066:

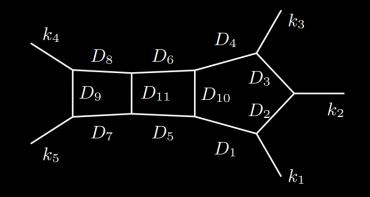

"This (using NeatIBP) improves the evaluation of the solution to the IBP relations, resulting in both a speed up in the finite-field sampling of the rational coefficients of the amplitudes and in a reduction of its memory footprint (by around 8 times and 3 times, respectively, for the leading colour two-loop five-particle amplitudes)."

Application of NeatIBP: Three-loop-five-point diagrams

Yuanche Liu, Antonela Matija`si' c, Julian Miczajka, Yingxuan Xu, Yongqun Xu, Yang Zhang, 2411.18697

Analytic evaluation of the master integrals for the Pentagon-box-box diagram via differential equations

Target integrals: integrals needed for DE of master integrals

"On a laptop, NeatIBP finds about 85000 IBP identities in full kinematics dependence within several hours. These relations are sufficient to derive the differential equation. As a comparison, standard IBP tools would generate three orders of magnitude more IBP relations, which make the reduction computation impossible."

Algorithms and features in NeatIBP 1.0

Main new features in the NeatIBP 1.1

2025.02

1. The Kira+NeatIBP interface

2. The spanning cuts method

3. Algorithm of syzygy vector simplification

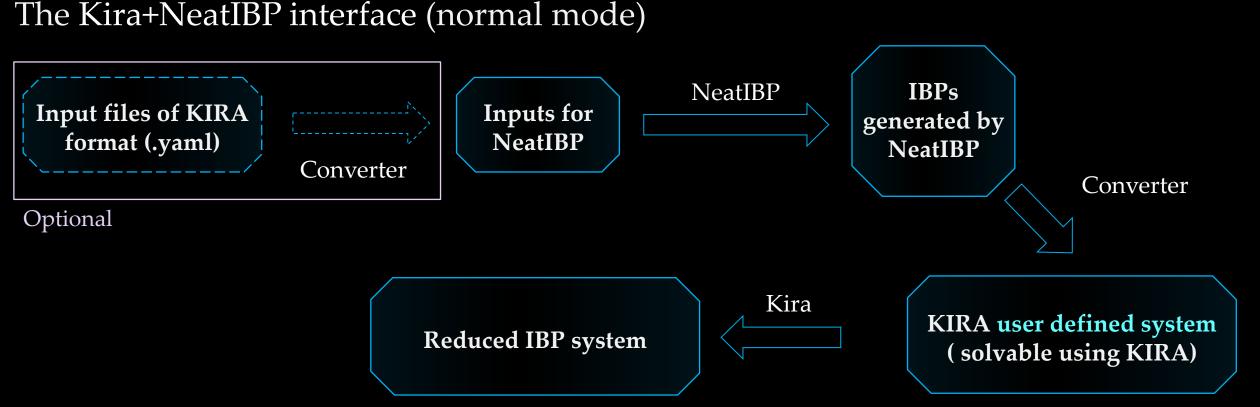

Currently, NeatIBP itself dose not perform IBP reduction

KIRA Comput.Phys.Commun. 230 (2018) 99-112, Comput.Phys.Commun. 266 (2021) 108024, etc. as a popular integral reduction software, is a very nice IBP solver for NeatIBP output.

Kira allows user to feed in linear systems of IBP relations (called user defined system) and then reduce them .

The Kira+NeatIBP interface is included in NeatIBP 1.1

In NeatIBP 1.1, to use Kira to reduce the IBP generated by NeatIBP, add the following commands into NeatIBP "config.txt"

PerformIBPReduction=True; IBPReductionMethod="Kira"; KiraCommand="/some/path/kira" FermatPath="/some/path/fer64"

Contents

Algorithms and features in NeatIBP 1.0

Main new features in the NeatIBP 1.1

1. The Kira+NeatIBP interface

2. The spanning cuts method

3. Algorithm of syzygy vector simplification

Generalized unitarity cuts in Baikov representation

$$I_{lpha_1,\cdots,lpha_n}|_{\mathcal{C}- ext{cut}} \propto \oint_0 \prod_{i\in\mathcal{C}} \mathrm{d} z_i \int \prod_{i
otin\mathcal{C}} \mathrm{d} z_i P^lpha rac{1}{z_1^{lpha_1}\cdots z_n^{lpha_n}}$$

Cuts change the integrals but preserve IBP relations

$$\sum_i c_i I_i = 0 \quad \longrightarrow \quad \sum_i c_i (I_i|_{\mathcal{C}- ext{cut}}) = 0$$

Cuts increases the number of *zero sectors* in a family

$$\mathcal{C}
ot \subseteq S \Rightarrow I|_{\mathcal{C}- ext{cut}} = 0, orall I \in ext{Sector } S$$

Spanning cuts method

A spanning cuts $\{C_i\}$ is defined so that for all nonzero sector S in a family, $\exists C_i$, such that $C_i \subseteq S$ $\{1,3\} - \operatorname{cut} \{2,4\} - \operatorname{cut}$

Step 1: Run NeatIBP on each cut

Current version of NeatIBP avoids cutting multiple propagators. Thus, for integrals such that $lpha_i=1, i\in \mathcal{C}$, $\mathcal{C} ext{-cut}$ means

 $|P
ightarrow P|_{z_i
ightarrow 0, i \in \mathcal{C}}$

Step 2: Reduce the IBP system on each cut Kira

Step 3: Merge the reduced IBP system of all cuts

Benefit:1. Split a difficult problem intosimpler pieces2. Parallelizable

Merging the spanning cut systems

$$\begin{split} I|_{\{1,3\}\text{-cut}} &= \sum_{i} c_{\{1,3\},i}^{1234} I_{i}^{1234}|_{\{1,3\}\text{-cut}} + \sum_{i} c_{\{1,3\},i}^{13} I_{i}^{13}|_{\{1,3\}\text{-cut}} \\ I|_{\{2,4\}\text{-cut}} &= \sum_{i} c_{\{2,4\},i}^{1234} I_{i}^{1234}|_{\{2,4\}\text{-cut}} + \sum_{i} c_{\{2,4\},i}^{24} I_{i}^{24}|_{\{2,4\}\text{-cut}} \\ & \swarrow \\ & \swarrow \\ & \text{merge} \end{split}$$

$$I = \sum_i c_i^{1234} I_i^{1234} + \sum_i c_i^{13} I_i^{13} + \sum_i c_i^{24} I_i^{24}$$

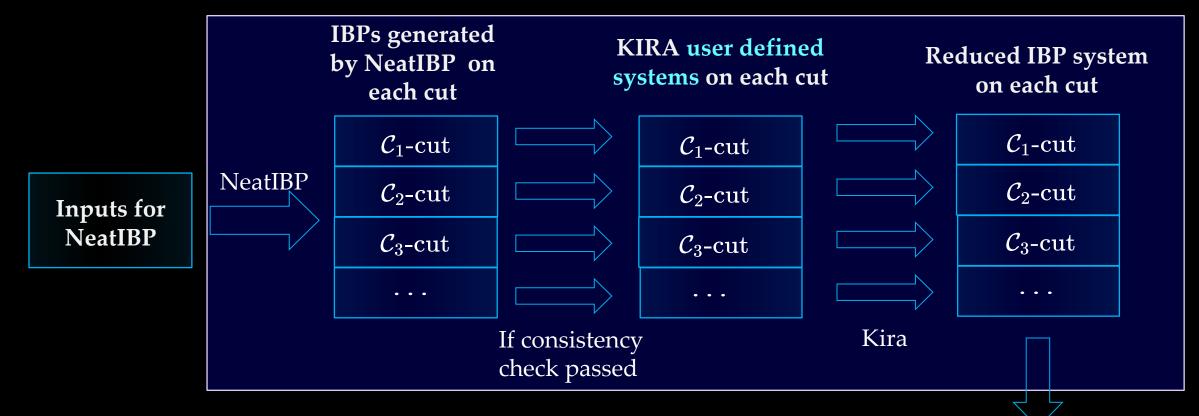

Currently, NeatIBP uses a "direct" merging strategy:

$$\left\{ egin{array}{ll} c_i^{13} = c_{\{1,3\},i}^{13} \ c_i^{24} = c_{\{2,4\},i}^{24} & ext{Consistency condition} \ c_i^{1234} = c_{\{1,3\},i}^{1234} = c_{\{2,4\},i}^{1234} \end{array}
ight.$$

NeatIBP checks consistency conditions before merging the spanning cut systems. This step cannot be omitted because the condition is NOT always guaranteed according to our observation. Inconsistency often observed in integrals with massive propagators.

The Kira+NeatIBP interface (spanning cuts mode)

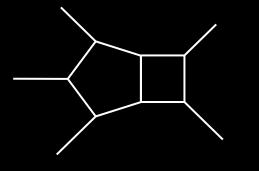

Parallelized by default

Config settings

PerformIBPReduction = True; IBPReductionMethod = "Kira"; KiraCommand = "/some/path/kira"; FermatPath = "/some/path/fer64"; SpanningCutsMode = True; Merged reduced IBP system A baby example of Kira+NeatIBP performance (with spanning cuts)

Two-loop five-point, with numerator degree 4

Running NeatIBP + Kira in spanning cuts mode:

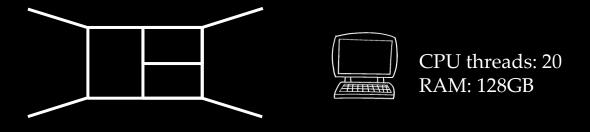

- 1. NeatIBP: Generates equations on 10 spanning cuts, time used: 8m
- 2. Number of equations: vary from 310 ~ 1583, on different cuts
- 3. Kira reduction time used: 5h

Running NeatIBP + Kira in normal mode:

- 1. NeatIBP: Generates 3708 equations spanning cuts, using 18m
- 2. Kira reduction time used: 24h

Another example of Kira+NeatIBP performance (with spanning cuts)

Three-loop four-point, with numerator degree 5

Running NeatIBP + Kira in spanning cuts mode:

- 1. NeatIBP: Generates equations on 22 spanning cuts, time used: 1h22m
- 2. Number of equations: $2k \sim 10k+$ or so, at most 35k, on different cuts
- 3. Kira reduction time used : 35m

Running NeatIBP + Kira in normal mode:

- 1. NeatIBP: Generates 113k equations spanning cuts, using 13h
- 2. Kira reduction time used: 2h30m

Symbolic IBP relation

Specific IBP relation

(# generators) \times (# seeds) = (# IBP relations)

~ hundreds large combinatorial numbers

Seeding cost ↑

Idea of the algorithm (taking no-dot integrals as example)

Treating tail integrals as zeros:

- 1. IBP relations containing only sub sector integrals will be discarded
- 2. This is equivalent to maximal cut (mc):

$$ext{ for } I \in ext{ sector } S$$
 , $\left. I
ight|_{ ext{mc}} := I
ight|_{S ext{-cut}}$

Simplification of syzygy generators via maximal cut

Delete generators that dose not change the "maximal cut" module $M|_{mc}$ defined as

$$M|_{\mathrm{mc}}:=\langle f_1|_{\mathrm{mc}},f_2|_{\mathrm{mc}},\cdots
angle \hspace{1.5cm} ext{for}\hspace{1.5cm}M=\langle f_1,f_2,\cdots
angle$$

Step 1: Using "maximal cut" Groebner basis

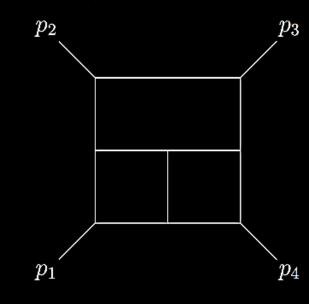

$$\left| G
ight|_{
m mc} := {
m GB}(M|_{
m mc}) = \langle g_1, g_2, \cdots
angle \qquad ext{ lifting } g_i = \sum_j c_{ij} f_i |_{
m mc}$$

Delete f_j in generators of M if $c_{ij} = 0, \forall i$ Because this means $f_j|_{
m mc}$ does not contribute to $M|_{
m mc}$

Step 2: Scanning

After step 1, sort the remaining generators from complex to simple $M' = \langle f'_1, \dots, f'_n \rangle$ Scanning *i* from 1 to *n*, if deleting f'_i does not change the GB of maximal cut module, then delete it.

Example

Summary

The integration-by-parts (IBP) reduction is one of the bottle-neck steps in the evaluation of multiloop Feynman integrals.

NeatIBP is an automated program generating small-size IBP system. It helps to reduce the computation cost of IBP reduction.

NeatIBP has been successfully applied to frontier problems, including two-loop amplitude computation in phenomenology and three-loop five-point Feynman diagrams.

We have displayed some new features of NeatIBP of the new version. They include:

1. The spanning cuts method :

Splitting the hard problem into simpler pieces.

- 2. The Kira interface:
 - Providing automated IBP solver.
- 3. Simplification algorithm of syzygy generators
