- Limits for axion dilute stars & miniclusters.

# Axion miniclusters & stars

Sensitivity on via density/gravity structural patterns can shed some light on boson DM properties.

#### Miniclusters:

Post-inflationary scenario causes inhomogeneities. A naïve estimate on the clump masses:

 $M\approx \frac{4\pi}{3}(1+\delta)\bar{\rho}H(T_{osc})^{-3}$ 

Or solve the density fluctuation's equation

$$\ddot{\delta} + 2H\dot{\delta} + \left(\frac{c_s^2 k^2}{a^2} - 4\pi G_N \bar{\rho}_a\right)\delta = 0$$

$$c_s^2 \approx \frac{k^2}{4m_a^2 a^2} \quad \text{See:} \quad {}^{1404.1938}_{1911.07853} \; {}^{1810.11468}_{2006.08637}$$

Or use N-body simulation.

1911.09417 2101.04177 2207.11276 2402.18221 Axion stars: Braaten

Localized (soliton) solutions under self-interaction / gravity

Oscillons ( $\dot{m}_a > 0$ ): astro-ph/9311037 Boson star (w gravity) 1406.6586

$$i\dot{\psi} = -\frac{\nabla^2\psi}{2m} - Gm^2\psi \int d^3x' \frac{\psi^*(\mathbf{x}')\psi(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} + \frac{\partial}{\partial\psi^*}V_{nr}(\psi,\psi^*)$$

## Gravitational interests in dark clumps/solitons

#### All evidences of DM are gravitational: should gravity tell us more?

>> Preferred as a cored DM halo <<

Galaxy scale dynamics: Disk thickening, stellar streams Church, J. P. Ostriker, and P. Mocz, 18' Amorisco and A. Loeb, 18' excludes  $m < 10^{-22}$  eV

Granularity above the de Broglie wavelength ~  $2\pi/mv$  L.Hui, 16' exclusion limit  $m \rightarrow 10^{-21}$ eV

Relaxation of old clusters, exclusion limit  $m \rightarrow 10^{-20} \sim 10^{-19} \text{eV}$ Bar-Or, Fouvry, and Tremaine, 19' Marsh and Niemeye, 19' Wasserman, 19' etc.

## The tidal relaxation

1. Density granularity (by solitons) above its coherent scale creates a randomized, noise-like gravitational potential.

2. Randomized tidal perturbations drive stars away from their orbits, leading to eventual evaporation of the system

3. Most effective on systems comparable or larger than the granularity size.

4. Unlike WIMPs, solitons have a macroscopically significant mass and contribute to relaxation.

DM granules  $(\lambda \sim (mv)^{-1})$  passing by a star perturb the star's velocity, raising the (average) stellar velocity dispersion:

$$\Delta v_{\star}^2 \propto \left(\frac{v_{\star}}{v_{DM}}\right)^4 \frac{t}{m_{DM}^3 r_{1/2}^4}$$

 $\sqrt{t}$  (Gyr<sup>1/2</sup>)

#### Smaller solitons, fluctuation at shorter scales.

Micro-structure domination of stochastic fluctuations when the mass function is steep

$$\frac{\mathrm{d}^2 n}{\mathrm{d}M\mathrm{d}c} = B_0 \left(\frac{M}{M_0}\right)^{\alpha} \delta \left[c - c_0 \left(\frac{M}{M_0}\right)^{\beta}\right]$$

Smaller solitons with shorter coherent
scales than the galaxy's observable subhalos:
\* less wavy DM like
\* Revealed at the size of wide binaries
\* Non-negligible size for binaries (< parsec).</li>
\*\* for binaries, the soliton size matters.

Boson stars form during gravitational collapse and grow over time. For recent simulations, see <u>2011.01333</u>, <u>1806.09367</u>, <u>1407.7762</u>, etc.

## Smaller (<< kpc) objects for small structures?

Our Galaxy hosts a population of very wide (up to ~ 1pc) binaries/candidates

#### Astrophysical binary system disruptions...

Binary survival under a dwarf-galaxy host halo's tidal field, Peñarrubia, Ludlow, et.al, 16'

Binary evaporation by encountering field stars (with impact parameter cut-off, exclude violent collisions)

$$\tau_{evap.} = \frac{m_1 + m_2}{m_*} \frac{\sigma}{16\sqrt{\pi}G\rho_* a \ln \Lambda}$$
$$\Lambda = \frac{b_{\max}v_{typ.}^2}{G(m + m_*)}$$

-> Can select isolated `halo-like' candidate binaries.

\* Newtonian point-point collisions (textbook)

\* Analogous to Brownian motion under random noise fluctuations

## Construction of the potential

An randomly distributed ensemble of solitons:

$$\rho(\vec{x},t) = \sum_{i} |\varphi(\vec{x} - \vec{x}_i - \vec{v}_i t)|^2 - \langle \rho \rangle$$

We aim at an analytic & accurate solution for binary evaporation by soliton's potential.

Soliton profiles are typically solved from S-P equation. Sample ansatzes:

$$\varphi(r) = \begin{cases} \frac{m_s^{\frac{1}{2}}}{(2\pi R^2)^{\frac{3}{4}}} e^{-\frac{r^2}{4R^2}}, & \text{Gaussian [27]};\\ \left(\frac{3m_s}{\pi^3 R^3}\right)^{\frac{1}{2}} \operatorname{sech}\left(\frac{r}{R}\right), & \text{Sech [16]};\\ \left(\frac{m_s}{7\pi R^3}\right)^{\frac{1}{2}} \left(1 + \frac{r}{R}\right) e^{-\frac{r}{R}}, & \text{Exponential linear (EL) [16]}. \end{cases}$$

normalized so that the density of the scalar field satisfies  $ho(r)\propto arphi(r)^2$ 

Evaporation: increments of relative motion's energy

For binary evaporation, the two-body system can be reduced to a well-defined single-body problem (plus some input from its COM motion)

$$\Delta E = \mu \vec{v_r} \cdot \Delta \vec{v_r} + \frac{1}{2} \mu (\Delta \vec{v_r})^2$$

 $\nabla \Phi$  drives the CM's random walk (can be small compared to  $v_{cm} \sim 10^{-3}c$ ) Tidal acceleration should be in proportional to  $\partial \wedge \partial \Phi$ 

$$\begin{split} \Delta \vec{v}_r &= \Delta \vec{v}_1 - \Delta \vec{v}_2, \\ &\frac{\langle \Delta \vec{v_r}^2 \rangle}{T} = \frac{1}{T} \left( \langle \Delta \vec{v}_1^2 \rangle + \langle \Delta \vec{v}_2^2 \rangle - 2 \langle \Delta \vec{v}_1 \cdot \Delta \vec{v}_2 \rangle \right) \\ &\frac{\langle \Delta E \rangle}{T} = \mu \frac{\vec{v}_r \cdot \langle \Delta \vec{v}_r \rangle}{T} + \frac{1}{2} \mu \left( \frac{\langle \Delta \vec{v}_1^2 \rangle}{T} + \frac{\langle \Delta \vec{v}_2^2 \rangle}{T} - \frac{2 \langle \Delta \vec{v}_1 \cdot \Delta \vec{v}_2 \rangle}{T} \right) \end{split}$$

\$\lambda\$ : spectral averaging over the soliton ensemble.
 1/T : time averages... should also take account of the binary's Keplerian motion.

#### `Fast' orbit: compact binaries

 $\frac{2\pi/\omega_b \ll \lambda_{\rm DM}/v_c}{2}$  Binary's orbital period is smaller than that of soliton variations, Orbital average 1/T before performing ensemble average.

$$\begin{aligned} \mathbf{1^{st} order: zero-result} & (\partial_t \vec{v}_r) \cdot \vec{v}_r = 2a \frac{\vec{r}_1 - \vec{r}_2}{|\vec{r}_1 - \vec{r}_2|} \left[ (\partial \wedge \partial) \Phi(\vec{x}_{CM}, t) \right] \cdot \vec{v}_r \\ \dot{E} &= \partial_t (\frac{1}{2}\mu\vec{v}^2) = \mu(\partial_t \vec{v}_r) \cdot \vec{v}_r &\approx (\vec{r}_1 - \vec{r}_2) \left[ (\partial \wedge \partial) \Phi(\vec{x}_{CM}, t) \right] \cdot \vec{v}_r \\ \dot{E} &= \mu \int \frac{d\vec{k}d\omega}{(2\pi)^4} (\vec{k} \cdot \vec{v}_r) \vec{k} \cdot (\vec{r}_1 - \vec{r}_2) \tilde{\Phi}(k, \omega) e^{i\vec{k} \cdot \vec{x}_{CM}} & \longleftrightarrow \langle \dot{E} \rangle = \frac{1}{T} \int_0^{T = \frac{2\pi}{\omega}} \dot{E} dt = 0 \end{aligned}$$

Closed (unperturbed) Keplerian orbits: odd power vanishes in orbital average

2<sup>nd</sup> order derivative:

$$\frac{\partial \dot{E}}{\partial t} = \mu \left( \langle \ddot{\vec{v}} \cdot \vec{v} \rangle + \langle \dot{\vec{v}} \cdot \dot{\vec{v}} \rangle \right) \qquad \Longrightarrow \qquad \mu \int k^2 (k^2 + \omega^2) \frac{\pi}{4} (a^2 + b^2) \tilde{C}_{\Phi}(\vec{k}, \omega) \frac{d\vec{k}d\omega}{(2\pi)^4}$$

Non-zero after orbital and angular averages: Contribution at 2<sup>nd</sup> (& higher) orders

#### Slow orbit: wide binaries

For wide binaries,  $v_r / v_{cm} \sim 10^{-3}$ . For a longer orbit period than the time scale of potential variations, one can take the ensemble average first, and leave the orbital parameters as constants.

Velocity change driven by the potential's gradient

$$\Delta \vec{v} = -i \int_0^T dt \int \frac{\vec{k} d^3 k d\omega}{(2\pi)^4} \Phi(\vec{k}, \omega) e^{i(\vec{k} \cdot \vec{r} - \omega t)}$$
To include the gravitational potential variations, expand out r(t) that travels across the DM background
$$\vec{r}(t) \approx \vec{r_0} + \vec{v_0}t + \int_0^t ds(t-s)\dot{\vec{v}}(s)$$

$$\exp\left[i(\vec{k} \cdot \vec{r} - \omega t)\right] = \exp\left[i\vec{k} \cdot \left(\vec{r_0} + \vec{v_0}t + \int_0^t d\tau(t-\tau)\dot{\vec{v}}(\vec{r_0} + \vec{v_0}\tau, \tau)\right) - i\omega t\right]$$

$$\approx e^{i\vec{k} \cdot (\vec{r_0} + \vec{v_0}t) - i\omega t} \left[1 + i\vec{k} \cdot \int_0^t d\tau(t-\tau)\dot{\vec{v}}(\vec{r_0} + \vec{v_0}\tau, \tau)\right]$$

The first term will vanish after the ensemble average. The only contribution comes from the second term Expand out the equation

$$\Delta \vec{v} = i \int_0^T dt \int_0^t d\tau (t-\tau) \int \frac{\vec{k} d^3 k d\omega}{(2\pi)^4} \int \frac{(\vec{k} \cdot \vec{k'}) d^3 k' d\omega'}{(2\pi)^4} \Phi(\vec{k},\omega) \Phi^*(\vec{k'},\omega') e^{i\vec{k} \cdot (\vec{r_0} + \vec{v_0}t) - i\omega t} e^{-i\vec{k'} \cdot (\vec{r_0} + \vec{v_0}\tau) + i\omega'\tau}$$

And make use of the relation:

$$\left\langle \Phi(\vec{k},\omega)\Phi^*(\vec{k}',\omega')\right\rangle = (2\pi)^4 C_{\Phi}(\vec{k},\omega)\delta^3(\vec{k}-\vec{k}')\delta(\omega-\omega')$$

We can make it an integral over the correlation function.

$$\langle \Delta \vec{v} \rangle = \int_0^T dt \int_0^t d\tau \int \frac{d^3k d\omega}{(2\pi)^4} \vec{k}^2 C_{\Phi}(\vec{k},\omega) \frac{\partial}{\partial \vec{v_0}} e^{i(\vec{k}\cdot\vec{v_0}-\omega)(t-\tau)}$$

The 1<sup>st</sup> order `diffusion' coefficient:

$$D[\Delta \vec{v}] = \frac{\langle \Delta \vec{v} \rangle}{T} = -\frac{1}{2} \int \frac{\vec{k} d^3 k d\omega}{(2\pi)^3} \vec{k}^2 C_{\Phi}(\vec{k},\omega) K'_T(\omega - \vec{k} \cdot \vec{v_0})$$
  
where  $K'_T(\omega) = \frac{\omega T \sin(\omega T) - 2[1 - \cos(\omega T)]}{\pi \omega^3 T}$ 

## Correlation functions

Spectra of the two-point correlation functions for the density  $\rho$  and gravitational potential  $\Phi$ 

$$\langle \rho(\vec{r},t)\rho(\vec{r'},t')\rangle \equiv C_{\rho}(\vec{r}-\vec{r'},t-t')$$
$$\langle \Phi(\vec{r},t)\Phi(\vec{r'},t')\rangle \equiv C_{\Phi}(\vec{r}-\vec{r'},t-t')$$

Fourier trans.

$$C_{\rho}(\vec{r},t) = \int \frac{d^3k d\omega}{(2\pi)^4} C_{\rho}(\vec{k},\omega) e^{i(\vec{k}\cdot\vec{r}-\omega t)}$$

By Poisson Eq.  $\nabla^2 \Phi = 4\pi G \rho$ 

 $F(\vec{v}) = \frac{\rho_0}{(2\pi\sigma^2)^{\frac{3}{2}}} e^{-\frac{v^2}{2\sigma^2}}$ 

Small-sized solitons are more likely virialized so we assume a Maxwellian velocity distribution.

Performing an average over their *v*-distribution

$$C_{\Phi} = 16\pi^{2}G^{2}k^{-4}C_{\rho} \qquad C_{\rho}(\vec{k},\omega) = \frac{1}{m_{s}}\int d^{3}r d^{3}r' d^{3}v dt \rho(\vec{r})\rho(\vec{r'})F(\vec{v})e^{-i\vec{k}\cdot(\vec{r}+\vec{r'}+\vec{v}t)}e^{i\omega t}$$

$$\rho(k) \text{ is the F.T.}$$
of the soliton profile 
$$C_{\rho}(\vec{k},\omega) = \frac{1}{m_{s}}\rho^{2}(\vec{k})\rho_{0}\sqrt{\frac{2\pi}{k^{2}\sigma^{2}}}e^{-\frac{\omega^{2}}{2k^{2}\sigma^{2}}}$$
16

Density corr. function with soliton profile and Maximillian velocity distribution

$$\begin{split} C_{\rho,\text{Gauss}}(\vec{k},\omega) &= m_s \rho_0 \sqrt{\frac{2\pi}{k^2 \sigma^2}} e^{-\frac{\omega^2}{2k^2 \sigma^2}} e^{-k^2 R^2}, \\ C_{\rho,\text{Sech}}(\vec{k},\omega) &= \frac{9m_s}{\pi^2 k^2 R^2} \left[ -2 + \pi k R \coth\left(\frac{\pi k R}{2}\right) \right]^2 \operatorname{csch}^2 \left(\frac{\pi k R}{2}\right) \rho_0 \sqrt{\frac{2\pi}{k^2 \sigma^2}} e^{-\frac{\omega^2}{2k^2 \sigma^2}}, \\ C_{\rho,\text{EL}}(\vec{k},\omega) &= \frac{4096m_s}{49} \frac{(28 + k^2 R^2)^2}{(4 + k^2 R^2)^8} \rho_0 \sqrt{\frac{2\pi}{k^2 \sigma^2}} e^{-\frac{\omega^2}{2k^2 \sigma^2}}. \end{split}$$

Time variance: relative motion btw (1) binary/solitons, (2) solitons in the bkg

Assuming  $\omega \approx k \cdot v$ , these functions (1) approach to a noise spectrum on large scales; (2) suppressed for  $k \cdot R \gg 1$ 

For binary evaporation, we repeat for the relative velocity  $\Delta \vec{v}_r = \Delta \vec{v}_1 - \Delta \vec{v}_2$ 

1<sup>st</sup> term in energy increment:

$$\frac{\vec{v_r} \cdot \langle \Delta \vec{v_r} \rangle}{T} = -\frac{1}{2} \int \frac{(\vec{k} \cdot \vec{v_r}) \vec{k}^2 d^3 k d\omega}{(2\pi)^3} C_{\Phi}(\vec{k},\omega) \left( K'_T(\omega - \vec{k} \cdot \vec{v_1}) - K'_T(\omega - \vec{k} \cdot \vec{v_2}) \right)$$
$$= -\frac{1}{2} \int \frac{(\vec{k} \cdot \vec{v_r}) \vec{k}^2 d^3 k d\omega}{(2\pi)^3} C_{\Phi}(\vec{k},\omega) \left( \delta'(\omega - \vec{k} \cdot \vec{v_1}) - \delta'(\omega - \vec{k} \cdot \vec{v_2}) \right)$$

For  $v_1 \approx v_2 \approx v_{CM}$  and  $|v_1 - v_2| \ll v_{CM}$ , this contribution is suppressed by  $v_r / v_{CM}$ 

The evaporation will be dominated by the  $2^{nd}$  order  $(\Delta v)^2$  term.

2<sup>nd</sup> term in energy increment:

$$\frac{1}{2}\mu\left(\frac{\langle\Delta\vec{v}_1^2\rangle}{T} + \frac{\langle\Delta\vec{v}_2^2\rangle}{T} - \frac{2\langle\Delta\vec{v}_1\cdot\Delta\vec{v}_2\rangle}{T}\right)$$

After some algebra...

$$\begin{aligned} \frac{\langle \Delta \vec{v}_1^2 \rangle}{T} &= \int \frac{\vec{k}^2 d^3 k}{(2\pi)^3} C_{\Phi}(\vec{k}, \vec{k} \cdot \vec{v}_1) \\ \frac{\langle \Delta \vec{v}_2^2 \rangle}{T} &= \int \frac{\vec{k}^2 d^3 k}{(2\pi)^3} C_{\Phi}(\vec{k}, \vec{k} \cdot \vec{v}_2) \\ \frac{\langle \Delta \vec{v}_1 \cdot \Delta \vec{v}_2 \rangle}{T} &= \int \frac{\vec{k}^2 d^3 k}{(2\pi)^3} C_{\Phi}(\vec{k}, \vec{k} \cdot \vec{v}_c) \cos[\vec{k} \cdot (\vec{r}_1 - \vec{r}_2)] \end{aligned}$$

[Use approximation]  $v_c \gg v_r, v_1 \approx v_2 \approx$ 

Finally, the tidal heating rate:

Remember  $|r_1 - r_2| \sim 2a$ , soliton size becomes relevant.

$$\frac{\langle \Delta E \rangle}{T} = \sqrt{\frac{2}{\pi}} \frac{\mu \rho_0 G^2}{m_s \sigma} \int \frac{d^3 k}{k^3} \rho^2(\vec{k}) e^{-\frac{(\vec{k} \cdot \vec{v}_c)^2}{2k^2 \sigma^2}} 2\left(1 - \cos\left[\vec{k} \cdot (\vec{r}_1 - \vec{r}_2)\right]\right)$$

This convolution factor takes care of scale dependence and reveals the difference btw the 2-body relative motion and the Brownian walk of a single-point particle (COM) under tidal perturbations.

### Evaporation time scale

$$\frac{\langle \Delta E \rangle}{T} = \frac{8\pi\mu\rho_0 G^2 m_s}{v_c} A\left(r_x, r_y, r_z, R, \frac{v_c}{\sigma}\right) \qquad \begin{array}{l} \text{Re-define our integrals and} \\ \text{make a similar-looking to} \\ \text{the classical formula} \end{array}$$
The relaxation time: 
$$t_d = \frac{|E_0|}{\left(\frac{dE}{dt}\right)_0} \int_0^1 \frac{dx}{A\left(\frac{R}{a_0}x, \frac{v_c}{\sigma}\right)} \qquad \begin{array}{l} \text{Solition size} \\ \text{Re-define our integrals and} \\ \text{make a similar-looking to} \\ \text{Solition size} \\ \text{Solition size}$$

$$t_d = 14.3 \operatorname{Gyr}\left(\frac{M_T}{0.5 \, M_\odot}\right) \left(\frac{a_0}{0.1 \, \mathrm{pc}}\right)^{-1} \left(\frac{v_c}{200 \, \mathrm{km/s}}\right) \left(\frac{m_s}{30 \, M_\odot}\right)^{-1} \left(\frac{\rho_0}{0.4 \, \mathrm{GeV/cm^3}}\right)^{-1} B\left(\frac{R}{a_0}, \frac{v_c}{\sigma}\right)$$

+ some dependence on the orbital plane orientation and soliton profiles.

# GAIA catalog: halo-like wide binaries

JCAP 02 (2025) 001

Catalog I & II limits for  $t_d = 10^{10}$  yr under solitons' tidal perturbation. (Blue bands) solutions for ALPs with potential:  $V(a) \sim -m_a^2 f_a^2 \cos(a/f_a)$ 

#### Binary disruption bounds for ALP minicluster halos

Denser models of MCH indicate for more significant disruption effect.

#### Phys.Rev.D 111 (2025) 4, 043042

Diffuse: low concentration,  $c \sim 10$ , larger MC size

Dense: high concentration,  $c \sim 10^4$ , compact MCs

Isolated: MCs do not clump into MCHs

# Take home messages

- Interest in DM's gravitational imprints is on the rise.
- We provide an *analytic* treatment of binary evaporation by randomly distributed, spatially extended objects. A concise form factor incorporates scale dependence from the density profile.
- GAIA data contain some 2000+ high-probability, halo-like, a>0.1 pc candidates. Their survival yields observation sensitivity to tidal disruption from DM.
- For dilute axion stars, sensitivity extends into heavier ALP mass range (relative to other star systems)  $10^{-17} < m_a < 10^{-15}$  eV.
- Interferrence effects in density profiles?.
- More complicated dynamics beyond kinetic heating: soliton disruption, etc.

Gravity observations offer more insight about DM
