01

Motivation

Motivation

Photon-photon physics at CEPC

Two photon energy spectrum

$$\frac{d(f_1 f_2)}{d\tau} = \int_{\frac{1}{2}\ln\tau}^{-\frac{1}{2}\ln\tau} f_1(\sqrt{\tau}e^{y_{cm}}) f_2(\sqrt{\tau}e^{y_{cm}})$$

with WWA photon spectrum

$$f(x) = \frac{\alpha}{2\pi} \left(\frac{1 + (1-x)^2}{x} \ln\left(\frac{Q_{max}^2}{Q_{min}^2}\right) + 2m_e^2 \left(\frac{1}{Q_{max}^2} - \frac{1}{Q_{min}^2} \right) \right)$$

$$x = \frac{E_\gamma}{E_e}$$

$$Q_{max}^2 = (\theta_c \sqrt{S}/2)^2 (1-x) + Q_{min}^2$$

$$Q_{min}^2 = m_e^2 x^2 / (1-x)$$

Motivation

QCD at CEPC

Clean environment enable measurements
not possible at LHC

- No pileup,
- background under control

Motivation

Tcc Production: perturbative & non-perturbative

Perturbative creation
of (anti-)charm quarks

$$m_c \gg \Lambda_{QCD}$$

Non-perturbative transition
into (exotic) hadrons

$$\mu \ll \Lambda_{QCD}$$

Tcc: compact tetraquark

Tcc: charm-meson molecule

$$F = \frac{kq_1 q_2}{R_2}$$

$$d \cdot \sin \phi = k \lambda$$

$$v = v_o + at$$

02

Formulism

Formulism

Diquark fragmentation model

Step 1: the perturbative production of the (cc) -diquark, which is of the non-relativistic nature.

Step 2: the nonperturbative hadronization of colored (cc) -diquark into T_{cc} .

Note: this fragmentation contribution becomes dominant only in the large p_t region.

Formulism

Diquark fragmentation model

Step 1: (cc)-diquark production

- **Amplitudes:** amplitudes of diquark differ from those of quarkonium by a sign factor:

$$M_{diquark} = (-1)^{\rho+1} M_{meson}$$

ρ : counts of vector vertices in the reversed Fermion line

- **Color:** (cc)-diquark can be either color $\bar{3}$ or 6

$$C_{\bar{3} \times \bar{3}}^{ijkl} = \frac{1}{\sqrt{12}} (\delta_{ik} \delta_{jl} - \delta_{il} \delta_{jk})$$

$$C_{6 \times \bar{6}}^{ijkl} = \frac{1}{\sqrt{24}} (\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk})$$

Formulism

Diquark fragmentation model

Step 2: hadronization

- **Model I:** potential models, e.g. harmonic oscillator potential (HOP)

$$\mathcal{P}((cc)[n] \rightarrow T_{cc}[n]) \longrightarrow |\Psi_{T_{cc}[n]}(r=0)|^2 = \frac{|R_{T_{cc}[n]}(r=0)|^2}{4\pi}$$

- **Model II:** heavy diquark-antiquark symmetry (HDAS)

$$(cc)_{\bar{3}} \rightarrow T_{cc}(cc\bar{u}\bar{d}) \iff \bar{c}_{\bar{3}} \rightarrow \bar{\Lambda}_c^-(\bar{c}\bar{u}\bar{d})$$

$$\mathcal{P}((cc)[^3S_1]_{\bar{3}} \rightarrow T_{cc}[^3S_1]_{\bar{3}}) \longrightarrow |\Psi_{cc}(0)|^2 \times f(c \rightarrow \Lambda_c^+)$$

Note: transition probability in HDAS scheme is about 2.7% of that in HOP scheme.

03

Results

Results

Cross sections

Finding 1: cross sections increase with center-of-mass energy.

Finding 2: strong dependence on charm quark mass m_c , and hadronization models.

Finding 3: contribution from $[^3S_1]_{\bar{3}}$ state dominates, while that from $[^1S_0]_6$ is negligible.

SuperKEKB	$T_{cc}[^1S_0]_6$	$T_{cc}[^3S_1]_{\bar{3}}$	$T_{cc}[^3S_1]_{\bar{3}}$
$\sigma: \times 10^{-3} \text{ fb}$	(HOP)	(HOP)	(HDAS)
$m_c = 1.94$	0.13	20.94	0.57
$m_c = 1.7$	0.46	58.44	1.60
$m_c = 1.5$	1.24	134.94	3.68
CEPC	$T_{cc}[^1S_0]_6$	$T_{cc}[^3S_1]_{\bar{3}}$	$T_{cc}[^3S_1]_{\bar{3}}$
$\sigma: \text{ fb}$	(HOP)	(HOP)	(HDAS)
$m_c = 1.94$	3.46	124.94	3.41
$m_c = 1.7$	5.42	181.08	4.94
$m_c = 1.5$	8.47	261.52	7.14
ILC	$T_{cc}[^1S_0]_6$	$T_{cc}[^3S_1]_{\bar{3}}$	$T_{cc}[^3S_1]_{\bar{3}}$
$\sigma: \text{ fb}$	(HOP)	(HOP)	(HDAS)
$m_c = 1.94$	24.85	416.39	11.37
$m_c = 1.7$	35.15	577.87	15.78
$m_c = 1.5$	49.88	801.17	21.87

Results

Events

SuperKEKB, $\sqrt{s}=10.6$ GeV, $L=8\times 10^{35}$ cm⁻²s⁻¹: 5~10⁴ per year

CEPC, $\sqrt{s}=240$ GeV, $L=10^{34}$ cm⁻²s⁻¹: (0.7~27)×10³ per year

ILC, $\sqrt{s}=500$ GeV, $L=2\times 10^{34}$ cm⁻²s⁻¹: (0.7~17)×10⁴ per year

With branching fractions $Br(T_{cc} \rightarrow D^0 D^0 \pi^+) \approx 100\%$ $Br(D^0 \rightarrow K^- \pi^+) \approx 4\%$

SuperKEKB: 0~16 per year

CEPC: 1~43 per year

ILC: 11~272 per year

Experimental study of Tcc at CEPC and ILC is promising.

Results

Pt distribution

- CEPC data (small pt region) scales with $1/p_t^6$ which implies double parton fragmentation dominates.
- ILC data (large pt region) scales with $1/p_t^4$ which implies single parton fragmentation dominates.

Common
Feature

These are analogous to the charmonium production because of the diquark fragmentation model.

Results

Angle distribution

- SuperKEKB, CEPC and ILC have similar angle differential distributions.

04

Summary

Summary

- Conclusion 1: It is promising to study the inclusive T_{cc} production at CEPC and ILC.
- Conclusion 2: The pt distribution of T_{cc} exhibit analogous behaviour as charmonium: scales as $1/pt^4$ at large pt while scales as $1/pt^6$ at relative smaller pt .
- Outlook: Opportunities of studying multiquark exotic states at CEPC!

.....

What is at the end of multiquark states?
