- 4. Summary and outlook**

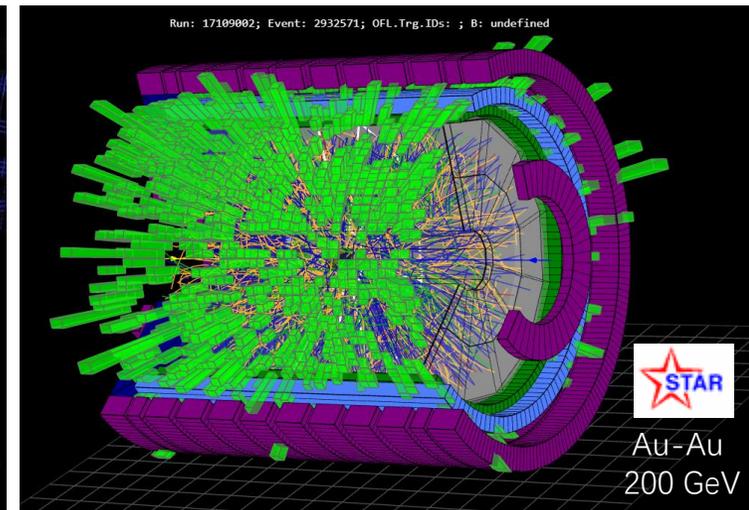

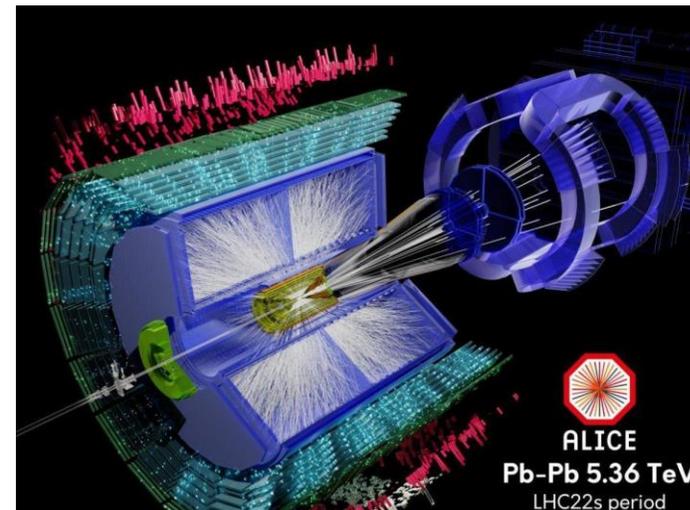

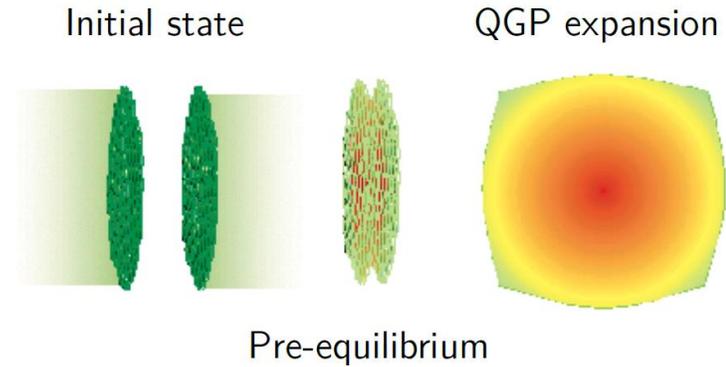

Introduction and motivation

Standard model and heavy-ion collisions

Standard Model of Elementary Particles

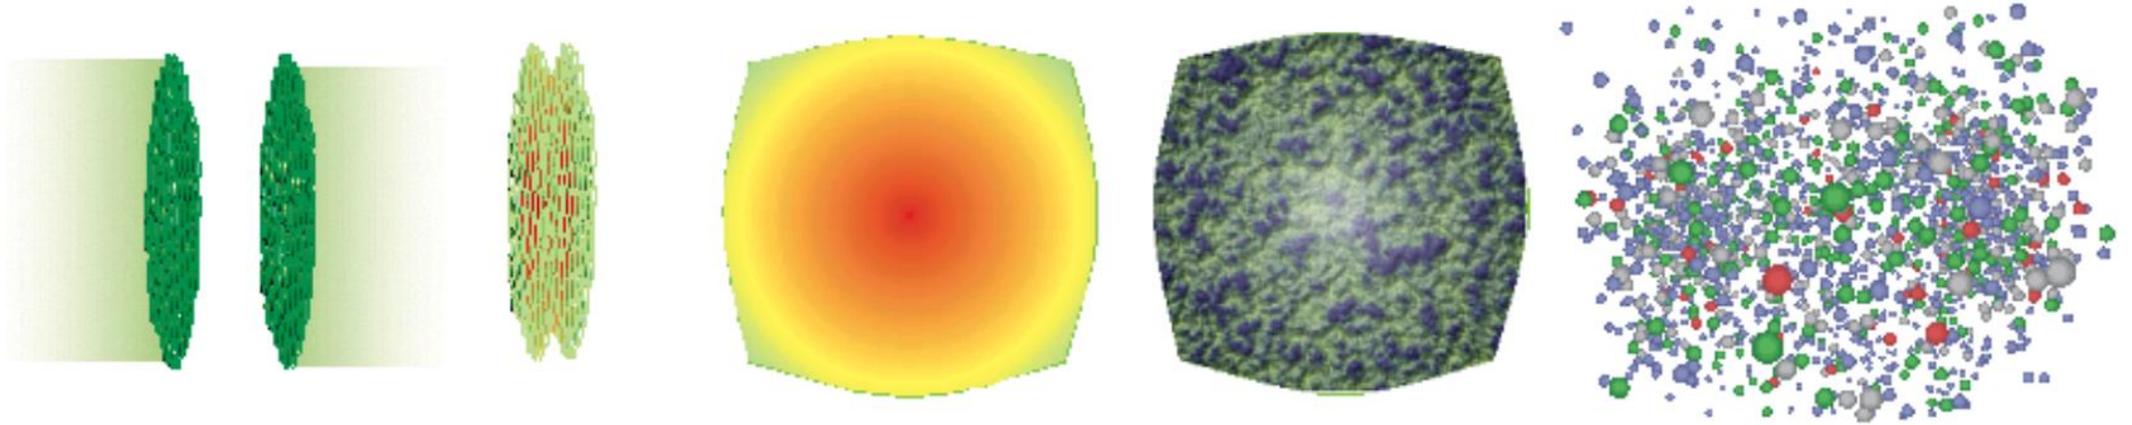

three generations of matter (fermions)			interactions / force carriers (bosons)		
	I	II	III		
mass	$\approx 2.16 \text{ MeV}/c^2$	$\approx 1.273 \text{ GeV}/c^2$	$\approx 172.57 \text{ GeV}/c^2$	0	$\approx 125.2 \text{ GeV}/c^2$
charge	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{2}{3}$	0	0
spin	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1	0
	u up	c charm	t top	g gluon	H higgs
	d down	s strange	b bottom	γ photon	
	e electron	μ muon	τ tau	Z Z boson	
	ν_e electron neutrino	ν_μ muon neutrino	ν_τ tau neutrino	W W boson	

QUARKS (I, II, III)
LEPTONS (e, μ , τ , ν_e , ν_μ , ν_τ)
GAUGE BOSONS VECTOR BOSONS (g, γ , Z, W)
SCALAR BOSONS (H)

QCD: Asymptotic freedom & Color confinement

Heavy-flavor probes

Hard scatterings

QGP

Hadronization

Hadronic interactions

pQCD

clean

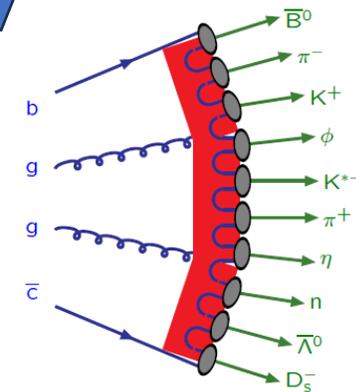

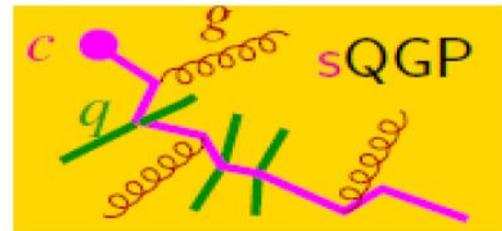

non-perturbative

c & b quarks

Large masses:

$m_Q \sim \text{GeV}$

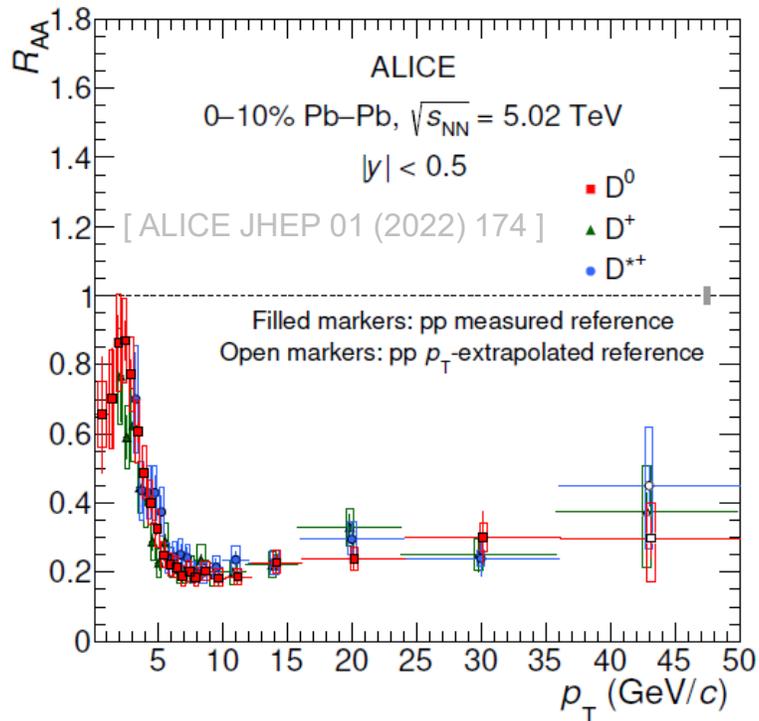

$\gg \Lambda_{\text{QCD}}, T_{\text{QGP}} \sim \text{MeV}$

pp baseline

Nuclear modification factor:

$$R_{AA}(p_T) = \frac{1}{\langle N_{coll} \rangle} \frac{dN^{AA}/dp_T}{dN^{pp}/dp_T}$$

6

Fragmentation of heavy-flavor (HF) hadrons:

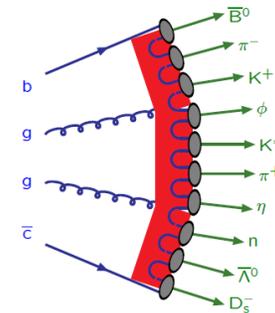

$$\sigma_{pp \rightarrow H_Q} = \sum_{i,j} f_i^{h_1} \otimes f_j^{h_2} \otimes \hat{\sigma}_{ij \rightarrow Q} \otimes D_Q^{H_Q}$$

PACIAE model: Ver. 4.0

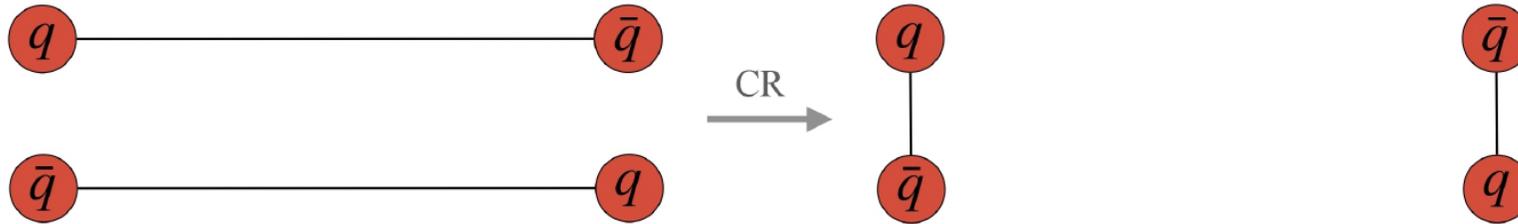

Simulation flow:

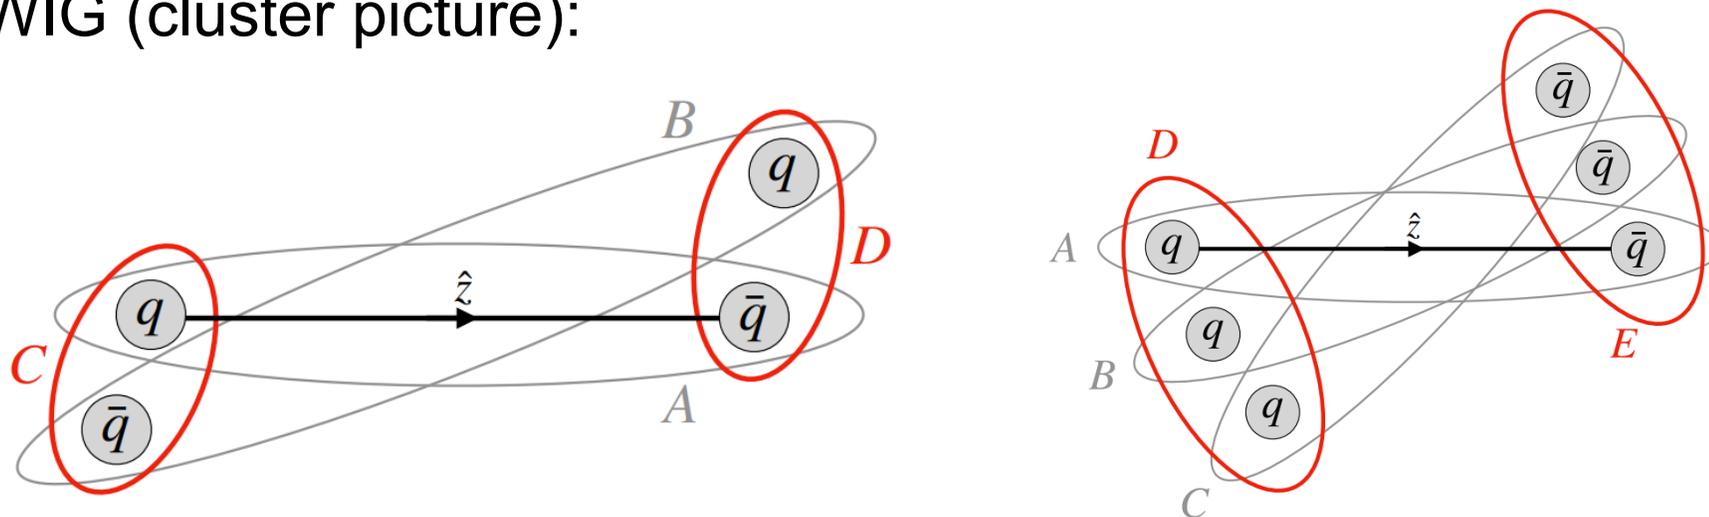

Color reconnection (CR)

The color charges (configurations) are allowed to be reconnected.

In PYTHIA (string picture):

In HERWIG (cluster picture):

Beyond-leading color (BLC)

SU(3) color algebra (QCD):

$$3 \otimes \bar{3} = 8 \oplus 1$$

color-triplet quark anti- color-octet gluon color-singlet

More generally:

$$N_c \otimes \bar{N}_c = (N_c^2 - 1) \oplus 1$$

Leading color (LC) / large N_c approximation: $N_c \rightarrow \infty$.

For MC implementation, no repeating colors will appear,

i.e. each colored particle is assigned a unique color/anticolor tag.

PYTHIA

HERWIG

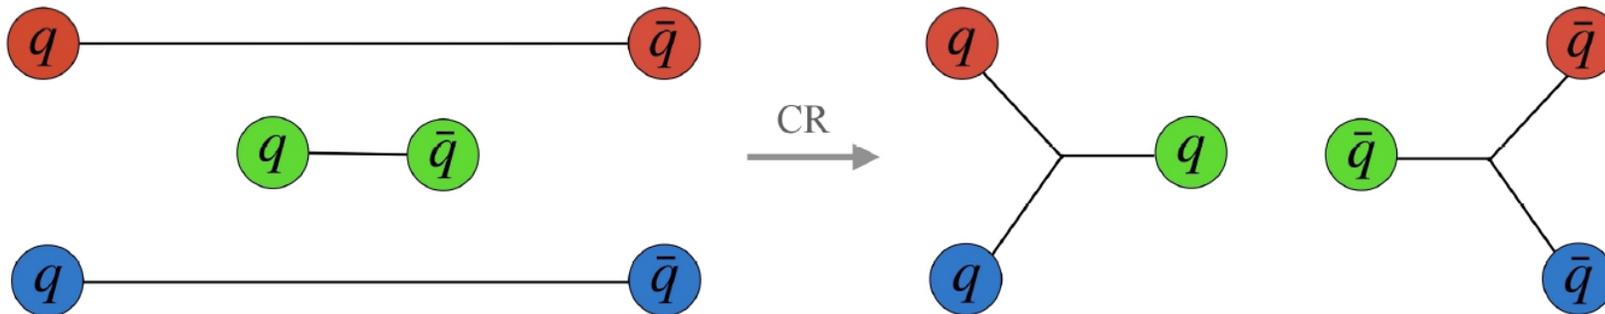

SHERPA

Beyond-leading color (BLC)

Recover/re-introduce the beyond-leading color (BLC) effect, in string picture, the **junction** topology is allowed by CR according to the QCD color rule (QCD-CR)!

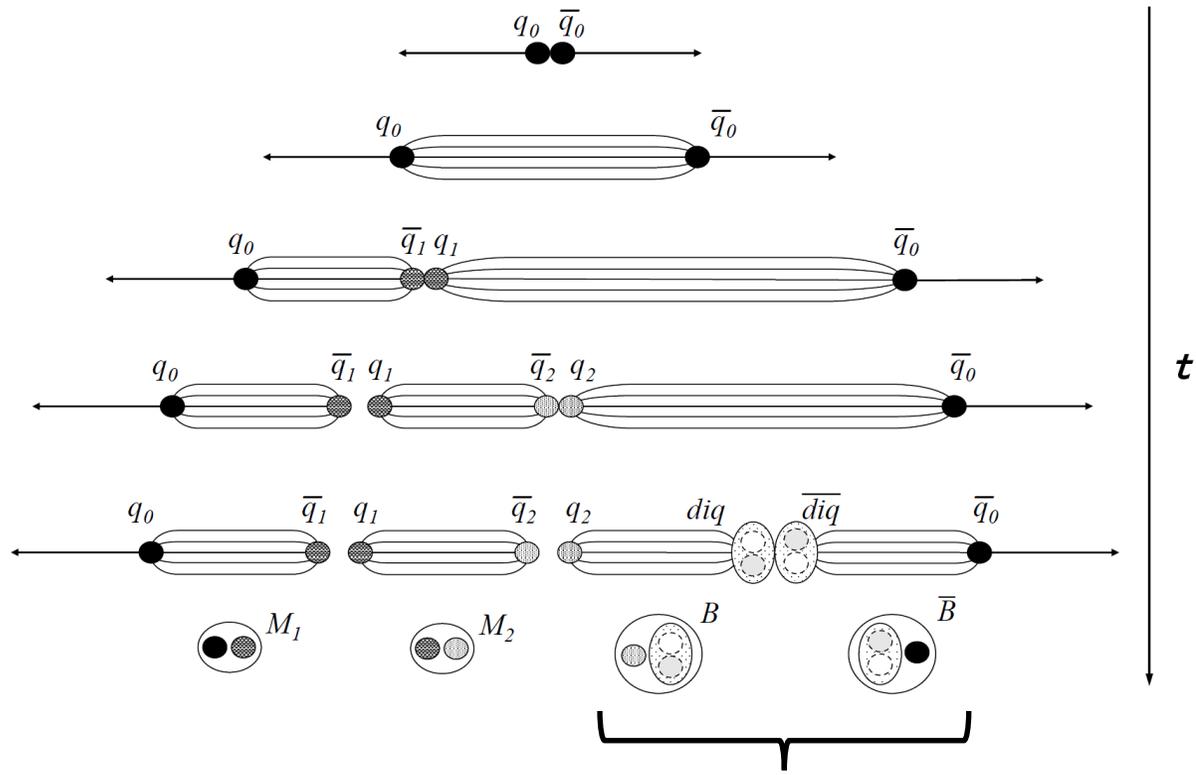

$$3 \otimes 3 \otimes 3 = 10 \oplus 8 \oplus 8 \oplus 1$$

String fragmentation

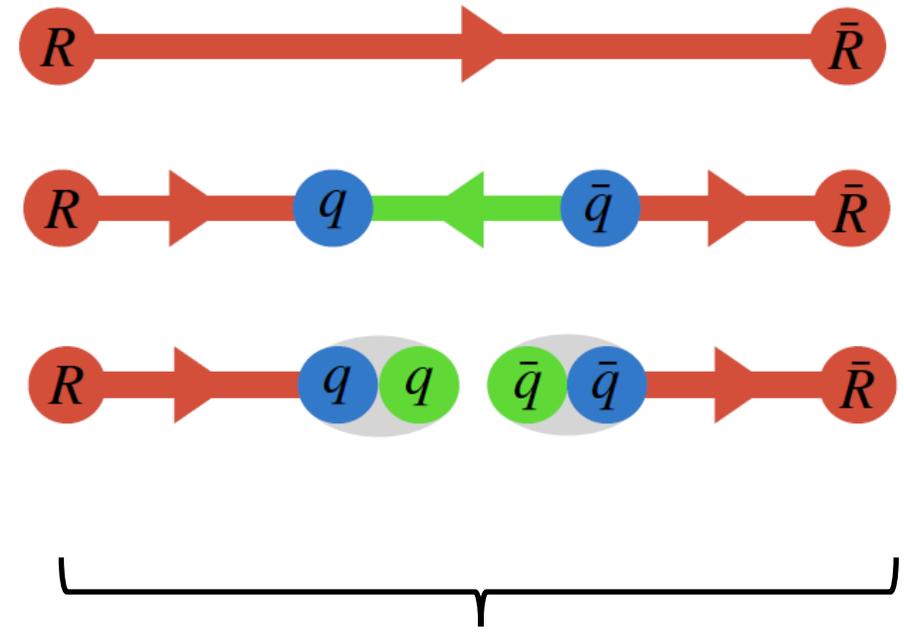

Baryon source in the String fragmentation model: **diquark formation!**

(1) Diquark excited from vacuum.

Normal baryon.

(2) Diquark combined by fluctuated $q(\bar{q})$, i.e. the popcorn mechanism.

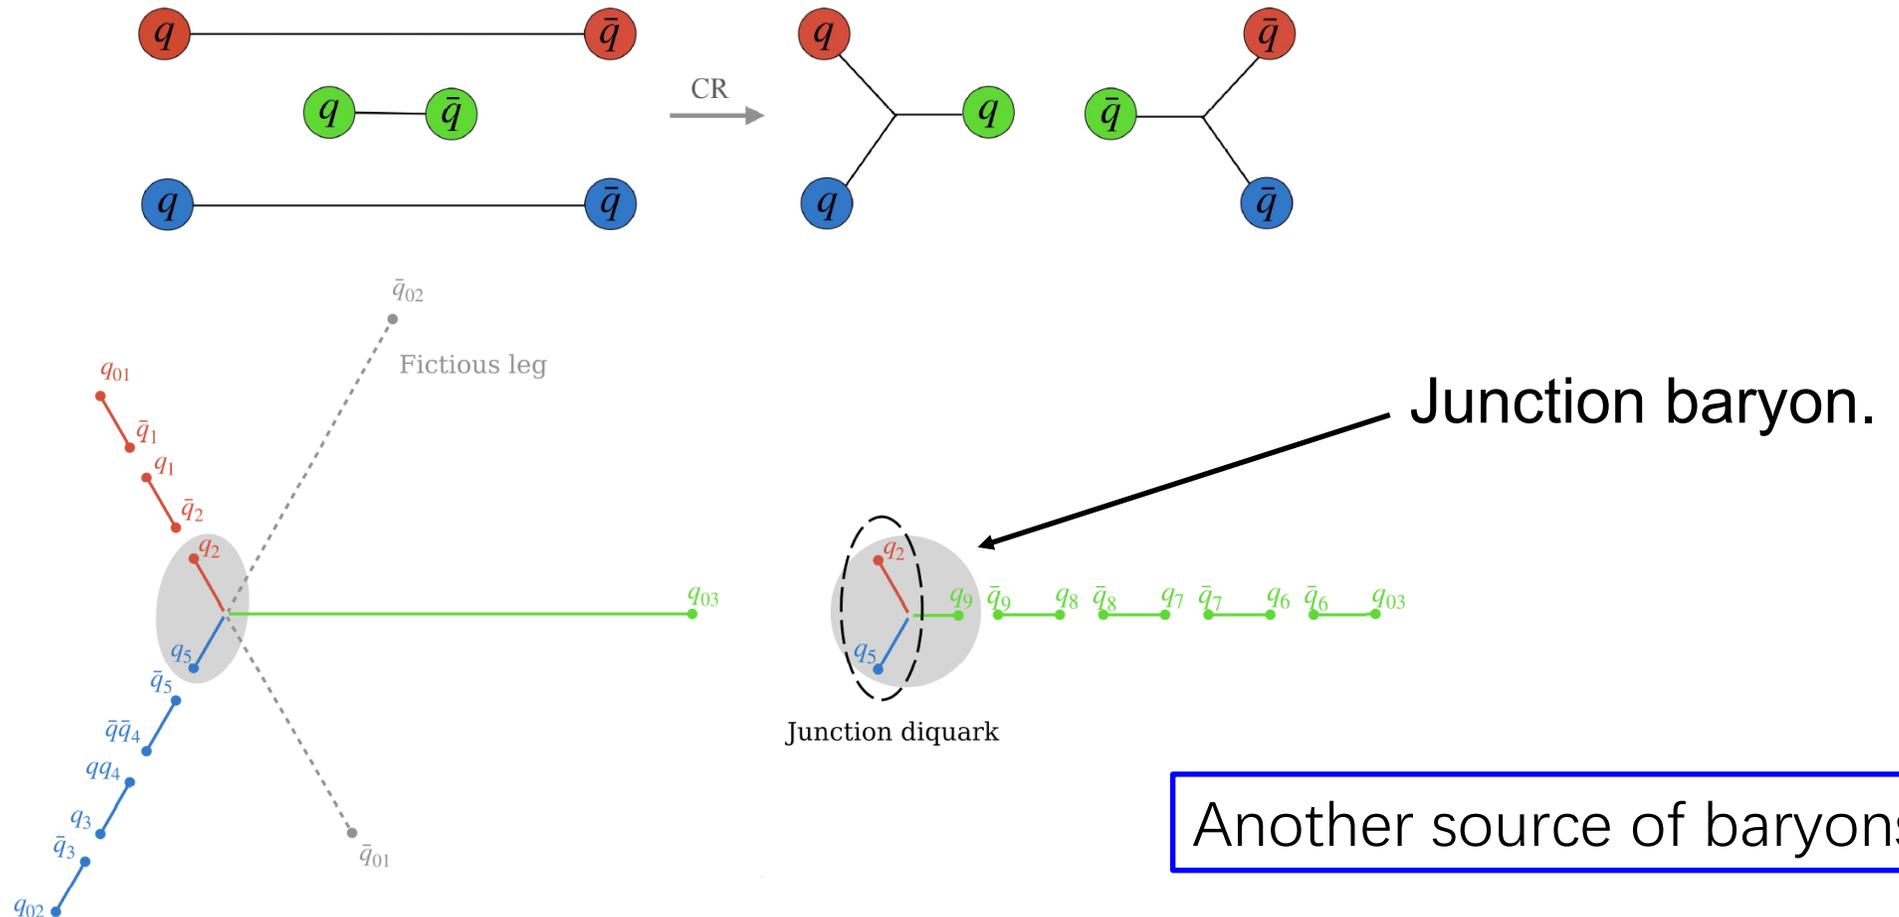

Popcorn baryon.

String fragmentation

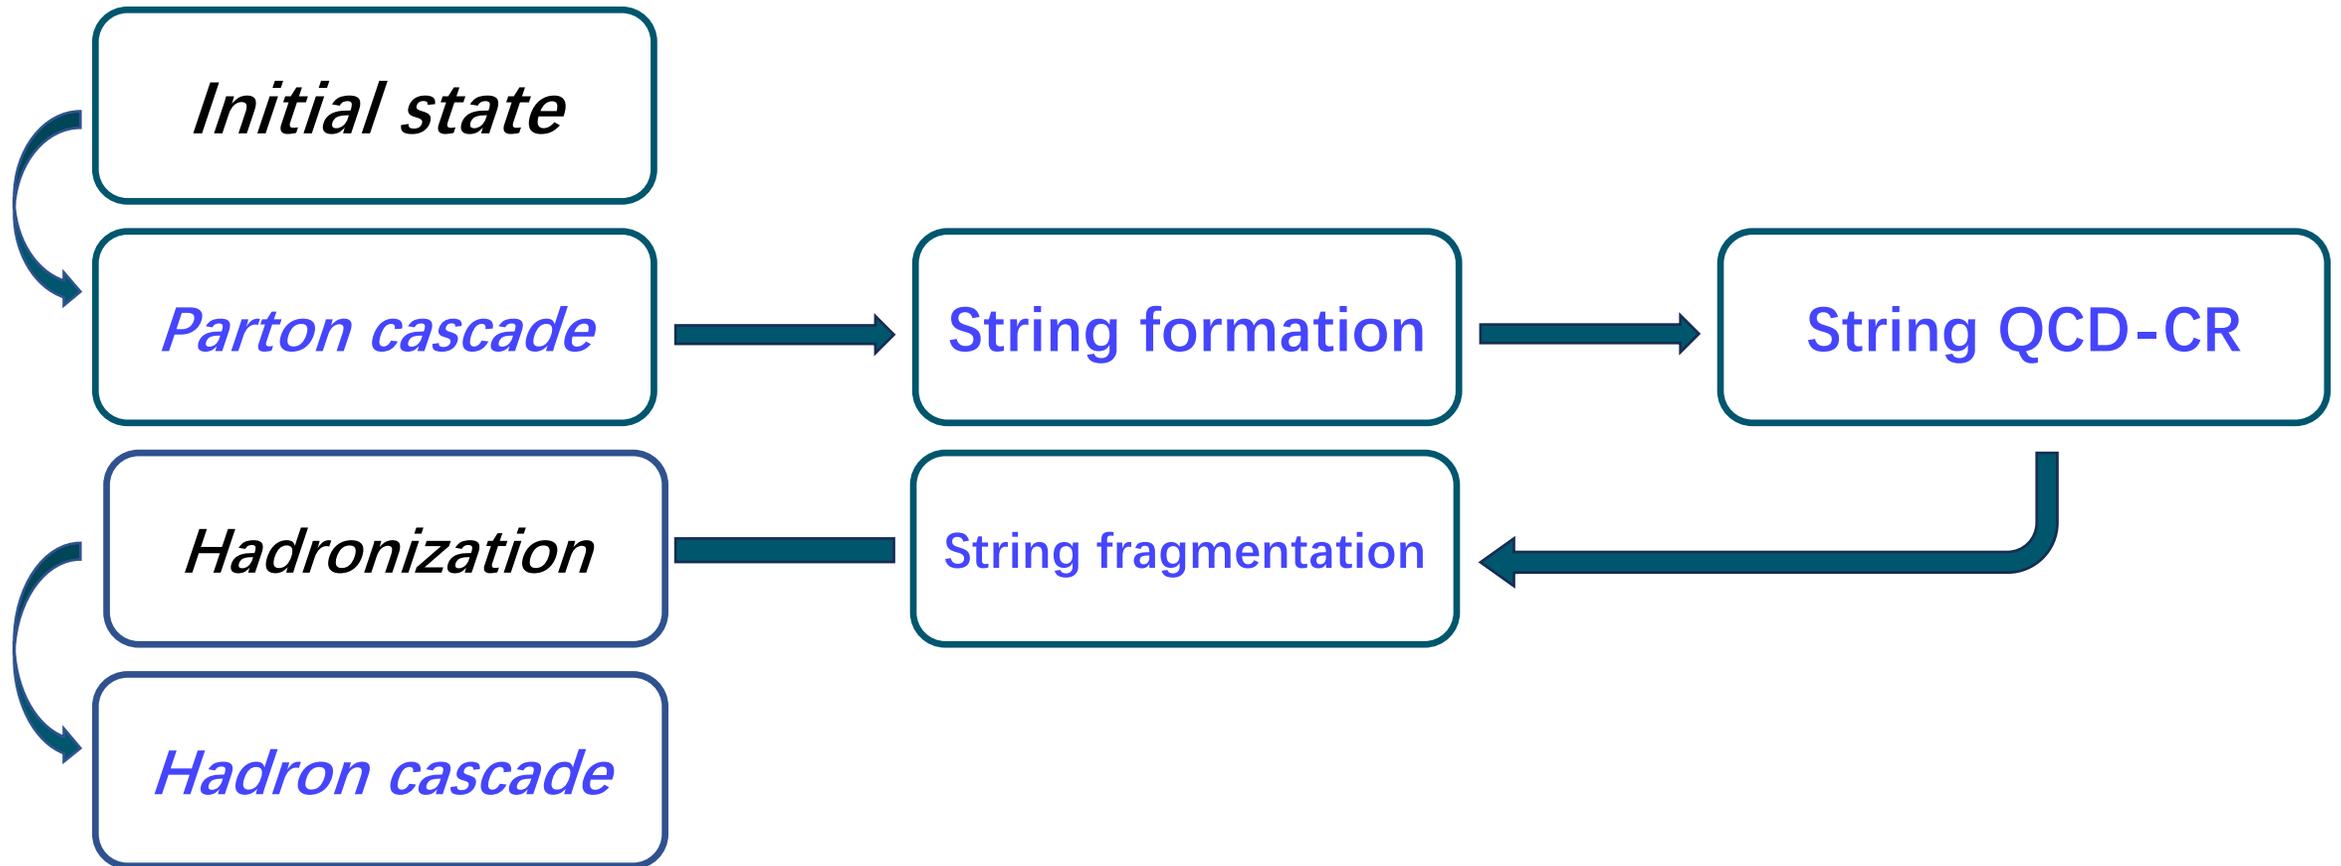

Baryon source in the String fragmentation model: **diquark formation!**

(3) Diquark combined by junction $q(\bar{q})$, stemming from QCD-CR + junction frag.

Implementation of QCD-CR in PACIAE4

PACIAE4:

Dynamical Space-Time Constrained QCD-CR in PACIAE4

(1) 3D spatial constraint:

For two dipoles to be reconnected, their distance:

$$\|r_{dip1} - r_{dip2}\| < d_{CR} = 4 \text{ fm}$$

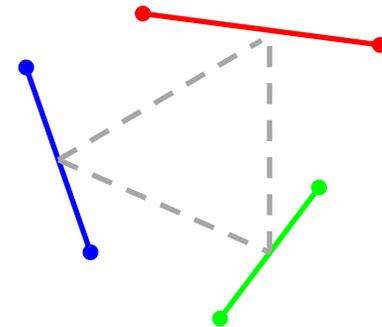

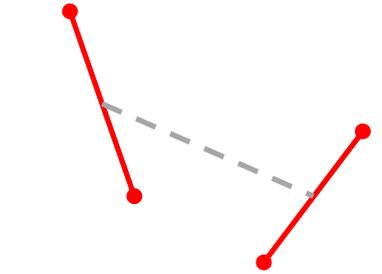

For three dipoles

$$\|r_{dip1} - r_{dip2}\| < d_{CR},$$

$$\|r_{dip1} - r_{dip3}\| < d_{CR},$$

$$\|r_{dip2} - r_{dip3}\| < d_{CR}$$

where the position of a dipole (r_{dip}) is represented by the midpoint between two parton ends (lab frame).

(2) Temporal constraint:

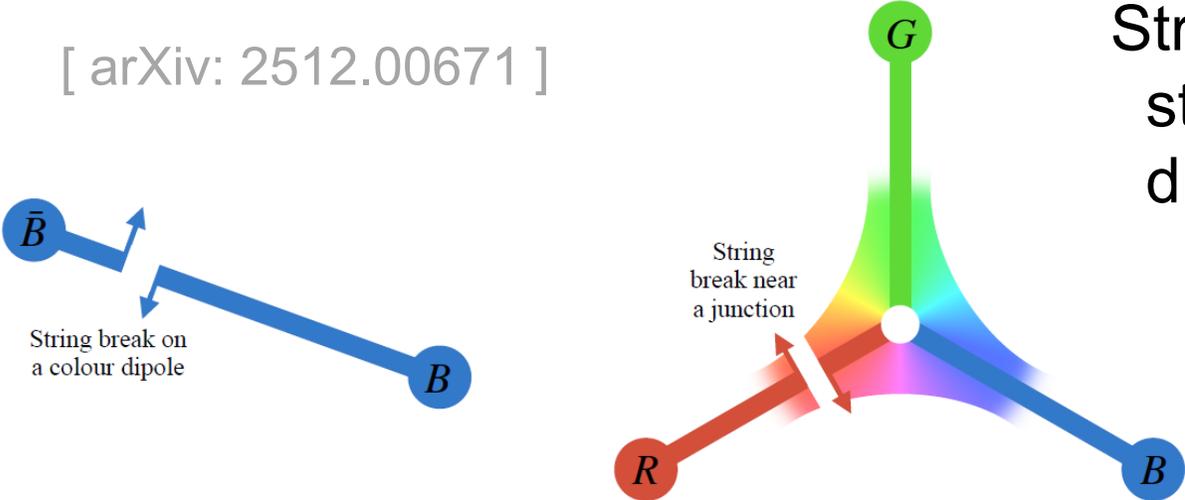

For dipoles to be reconnected, their ends should be at a same time point,

19

i.e. propagate partons to the maximum time among them before the distance checking.

Junction String Tension Enhancement

[arXiv: 2512.00671]

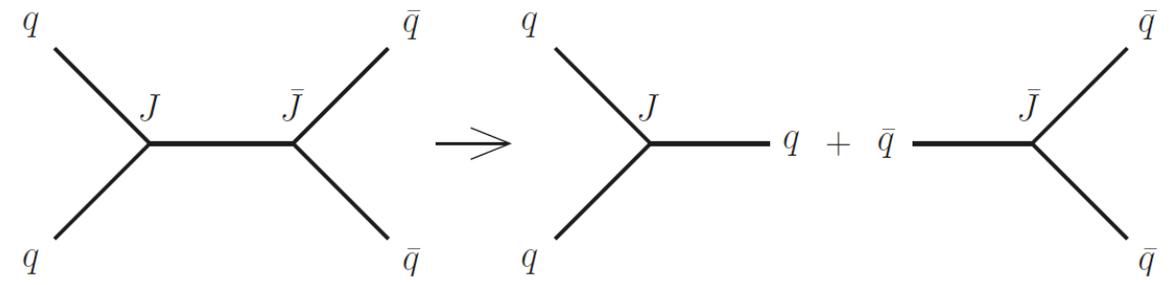

Strange junction: The excited probability ratio of strange $q\bar{q}$ over the u/d one **around** junction differs from that of the normal string.

$$P'(s : u/d) = P(s : u/d)^{1-J_s}$$

Instead, we use the string tension scaling:

$$P'_S = P_S^{\kappa_0/\kappa_{eff}}$$

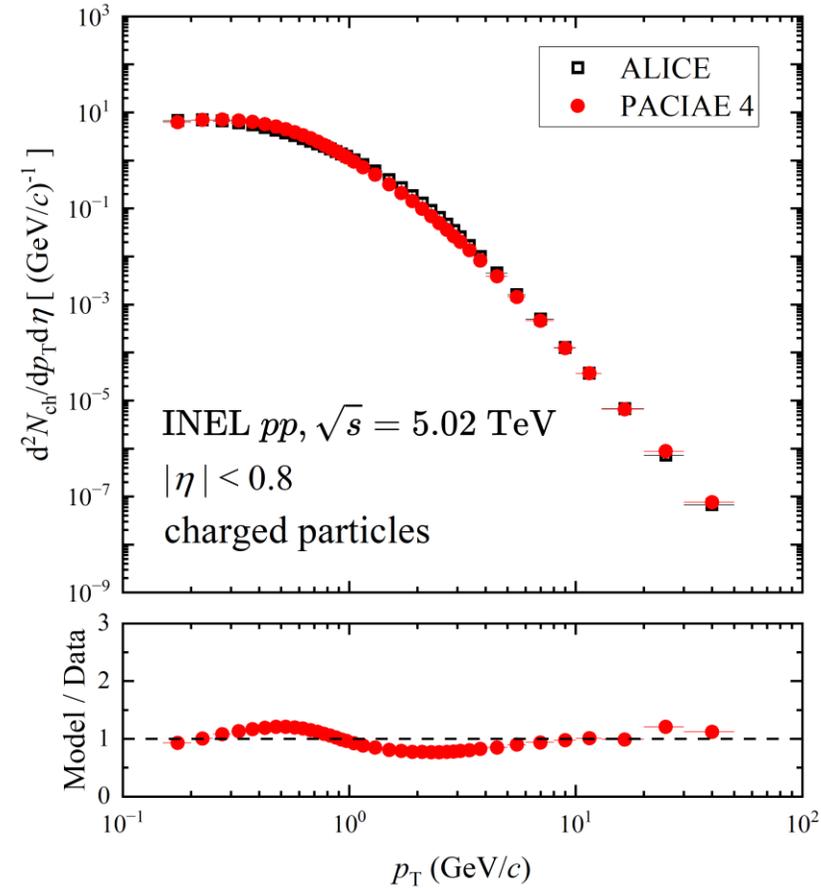

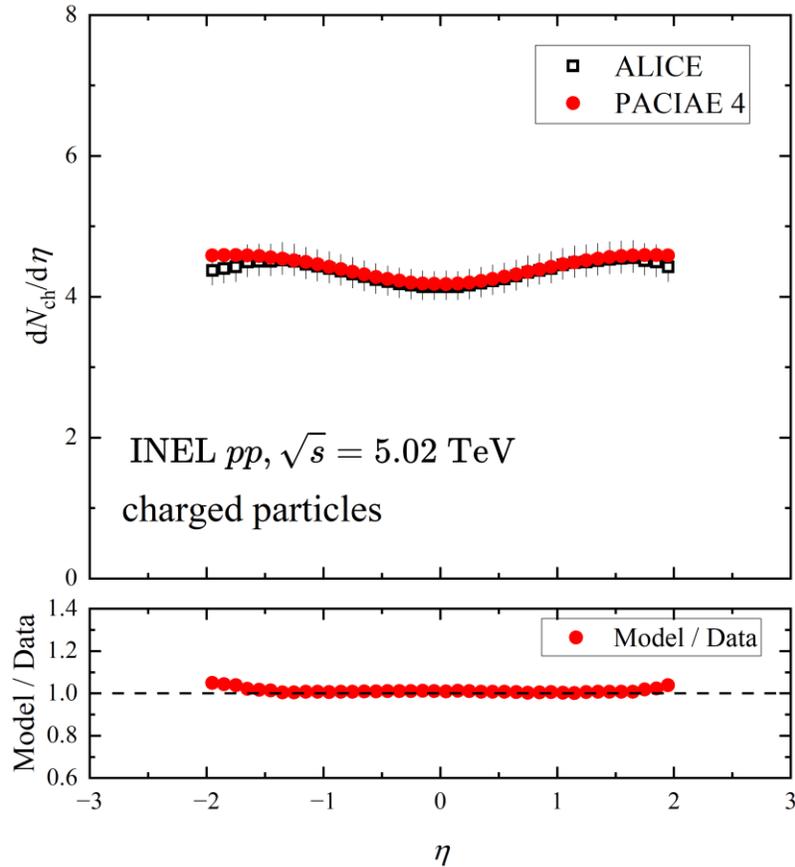

$$h := \kappa_{eff}/\kappa_0 (= 3)$$

Furthermore, we take the tension enhancement between the **junction-antijunction** into account, i.e. for the break to decouple junction-antijunction system.

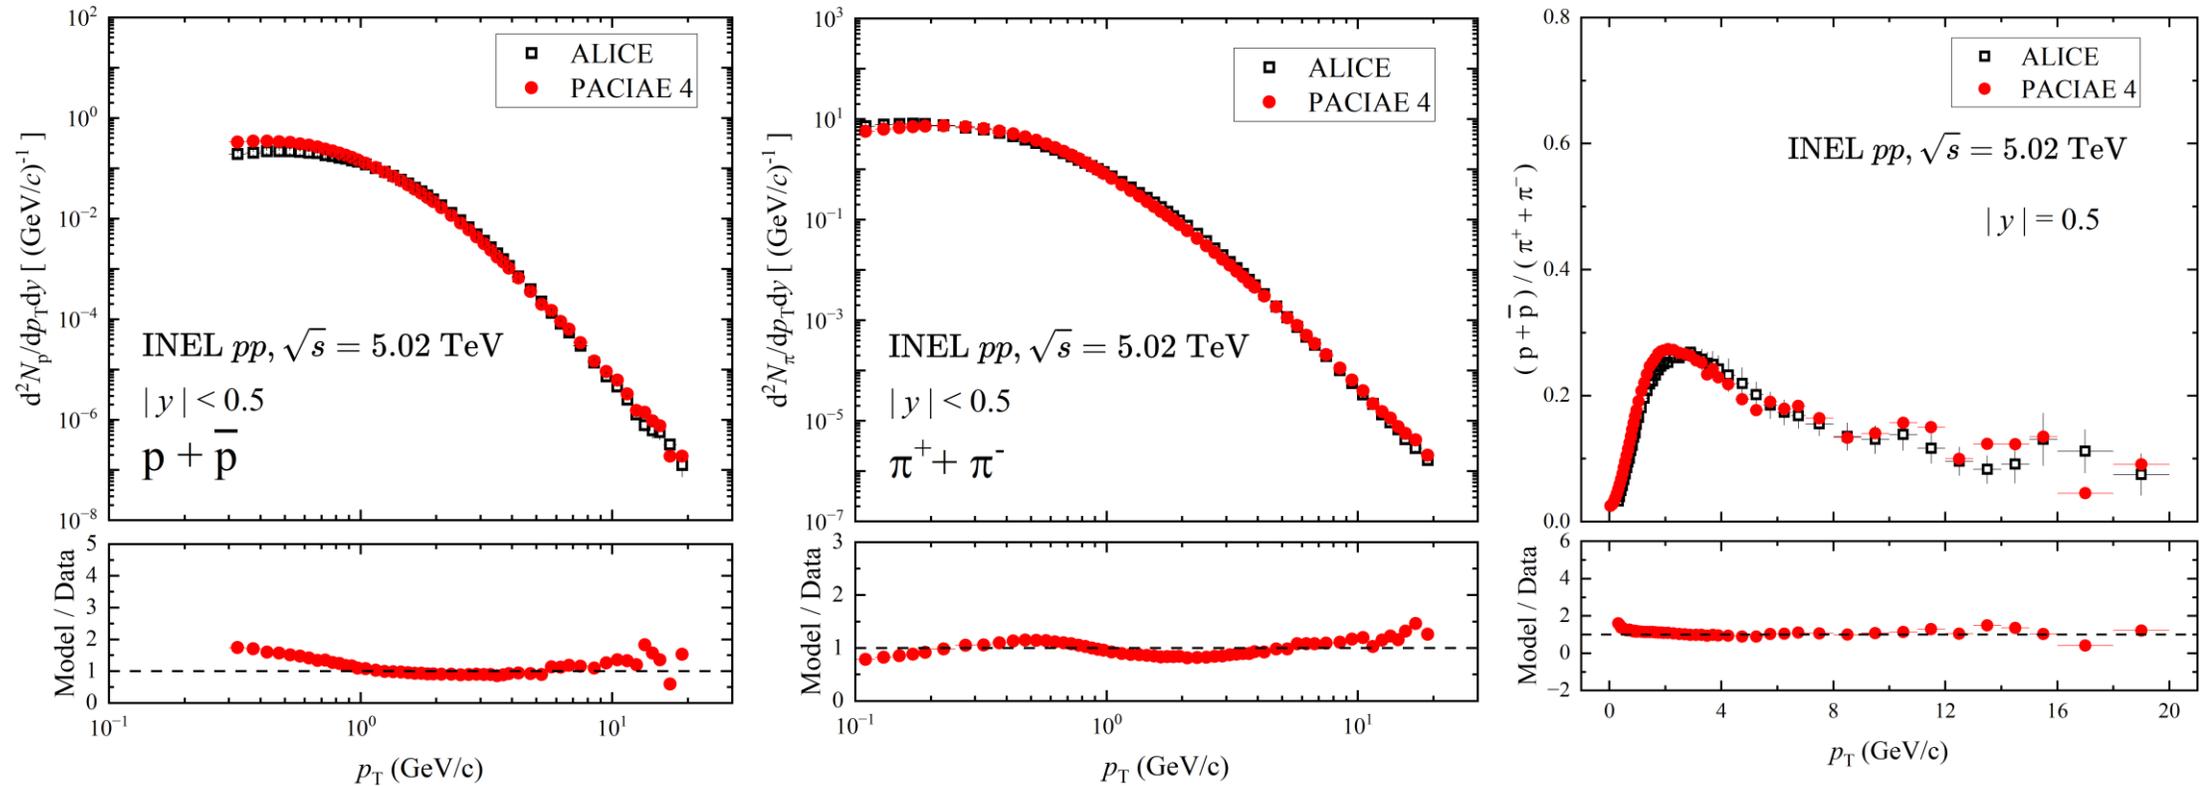

Production of open-flavor hadrons

Charged hadrons

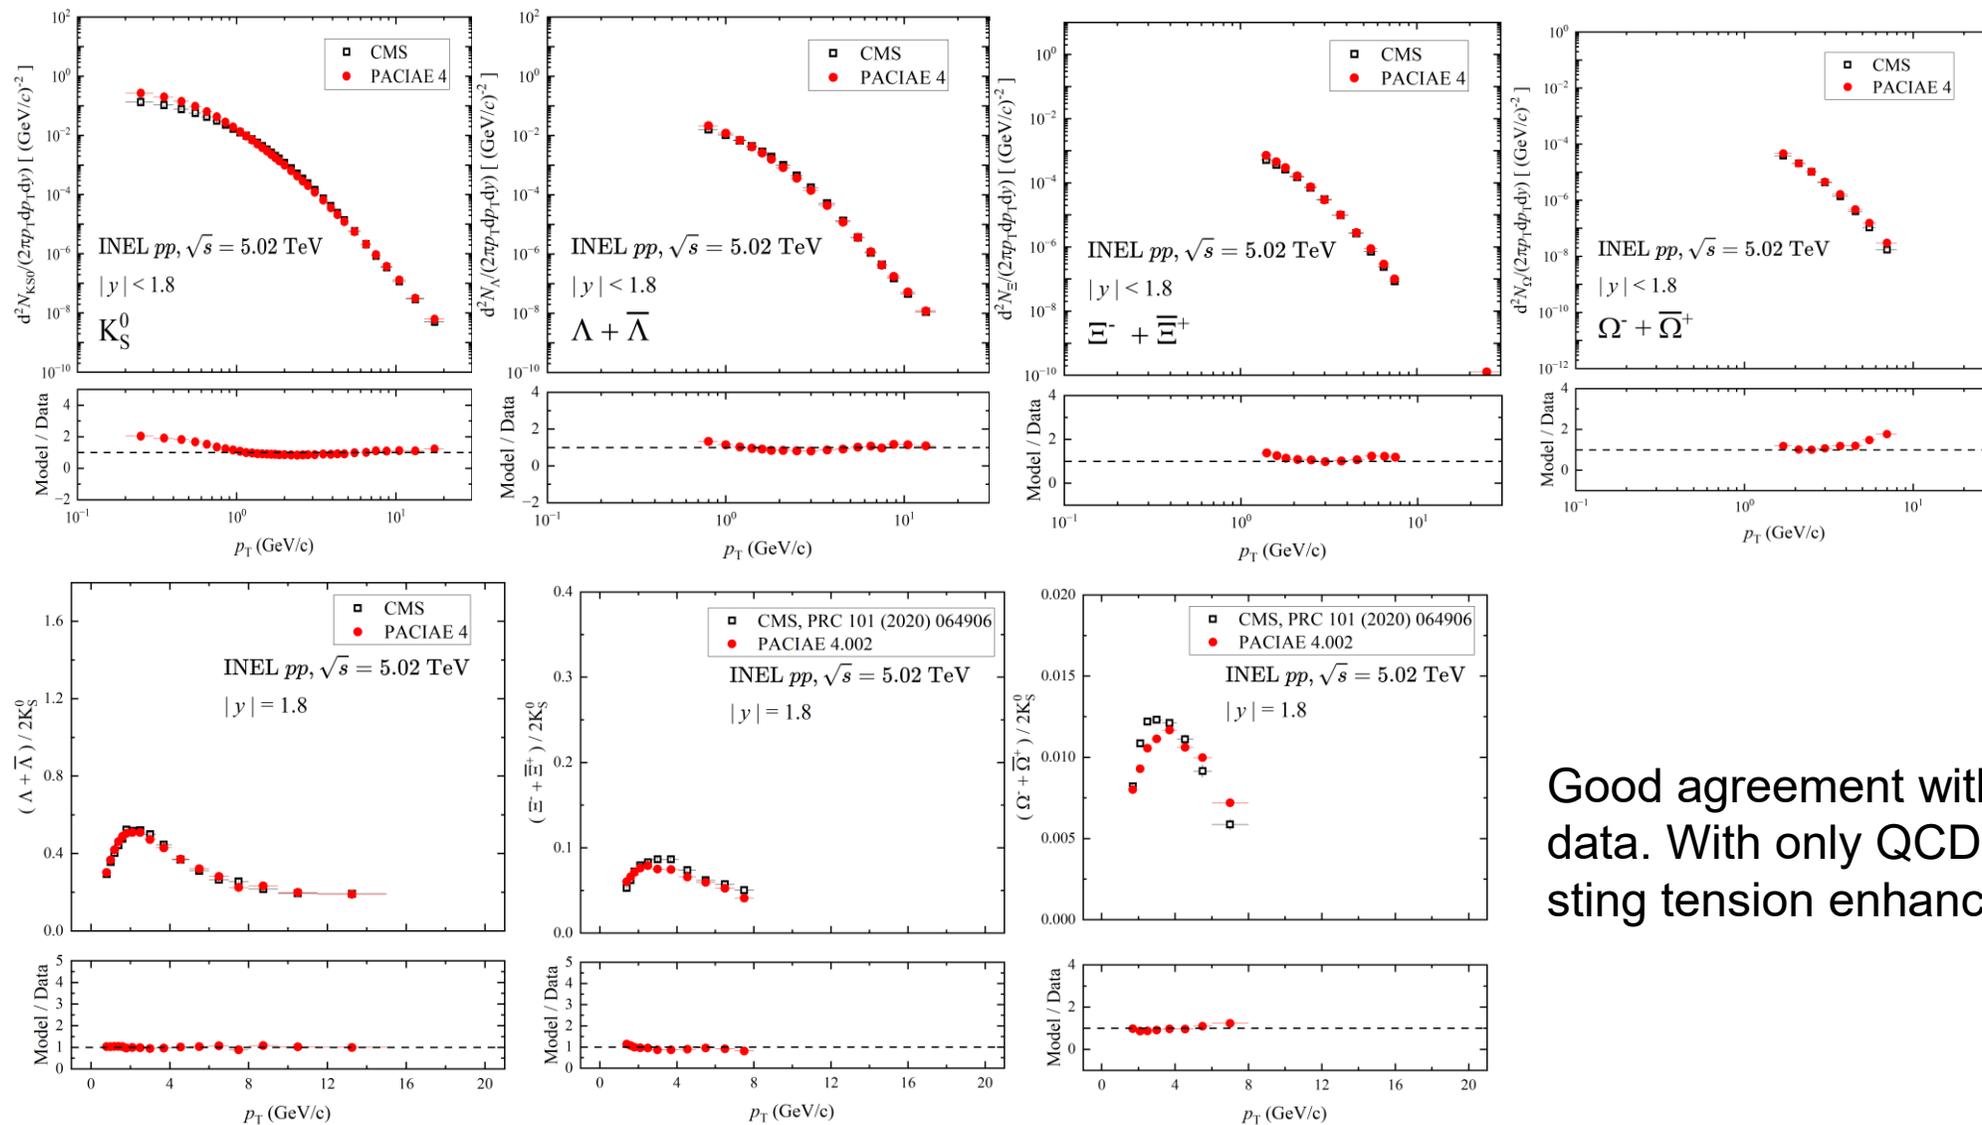

PACIAE4 well describes the charged particle data.

Light sector

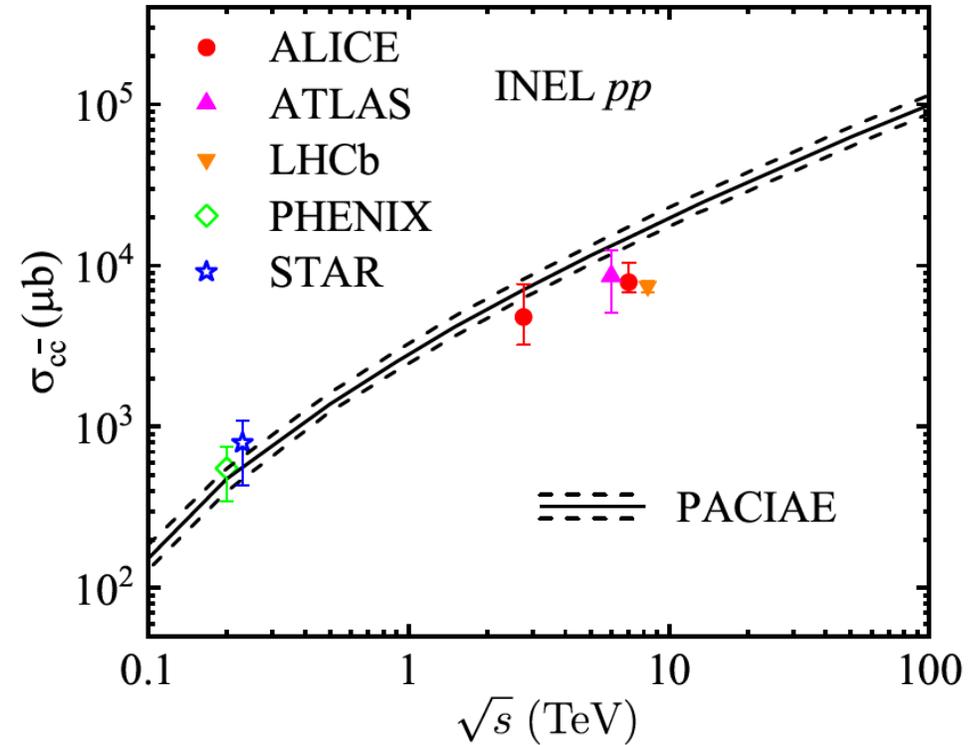

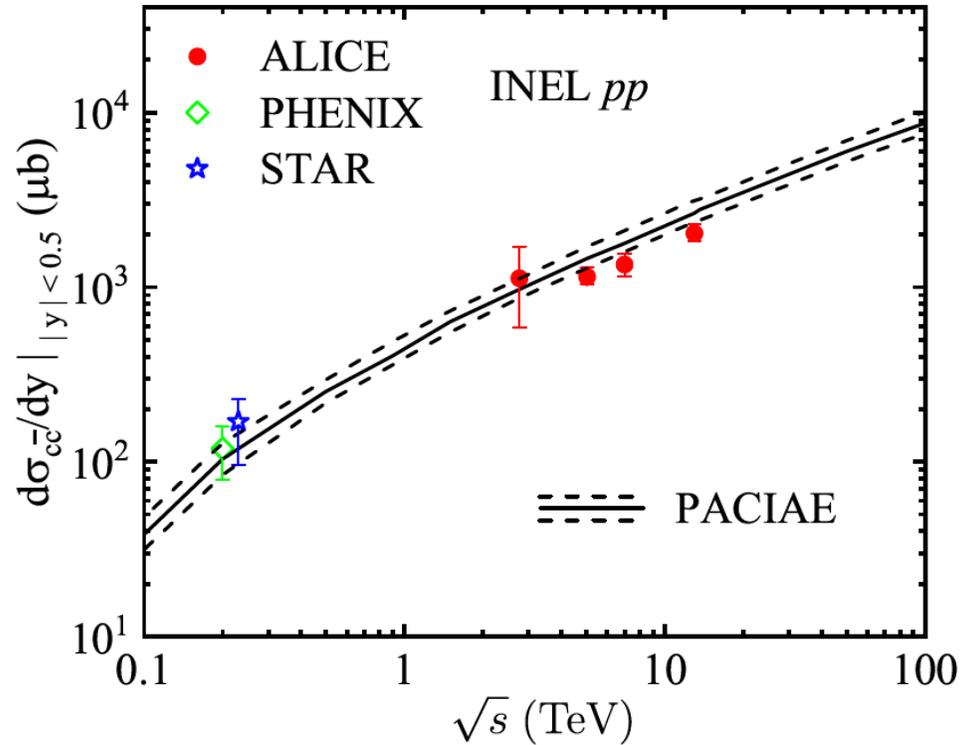

PACIAE4 well describes the light p and π data , along with the p/π ratio.

Strange sector

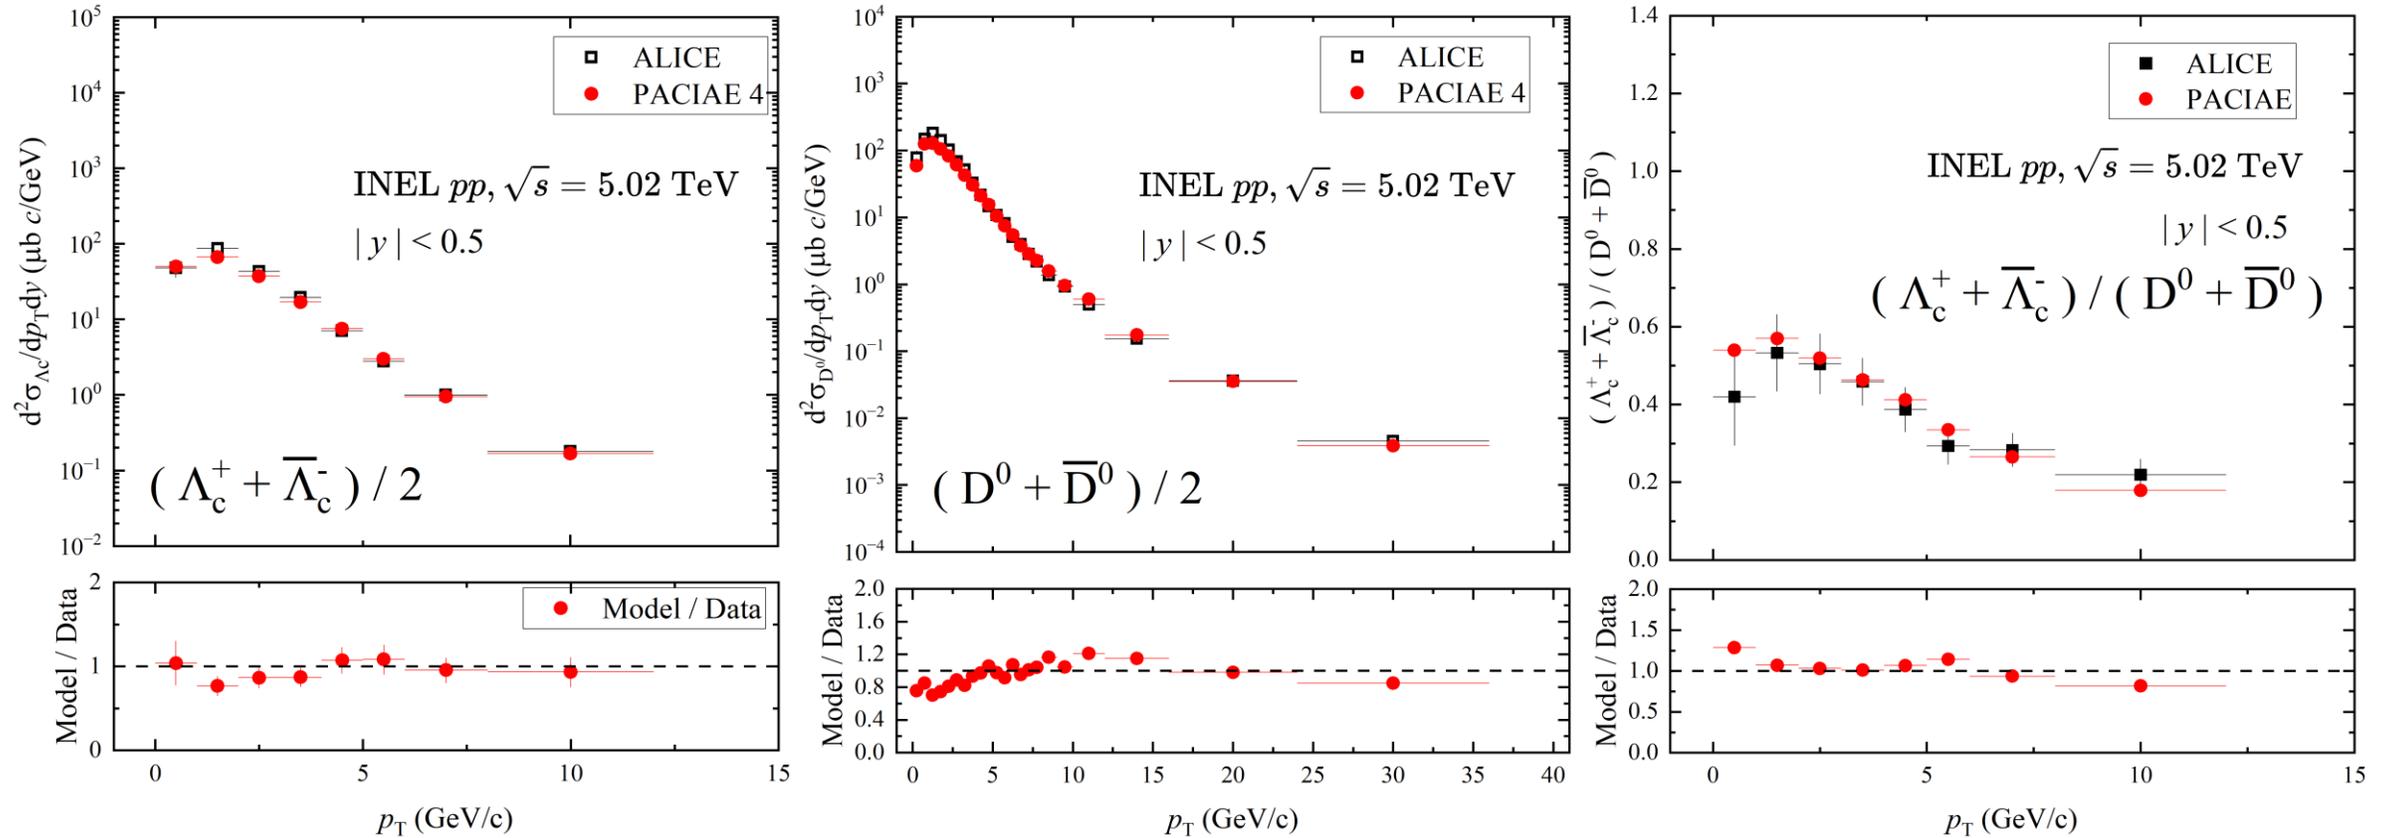

Good agreement with experimental data. With only QCD-CR + junction string tension enhancement!

Charm sector

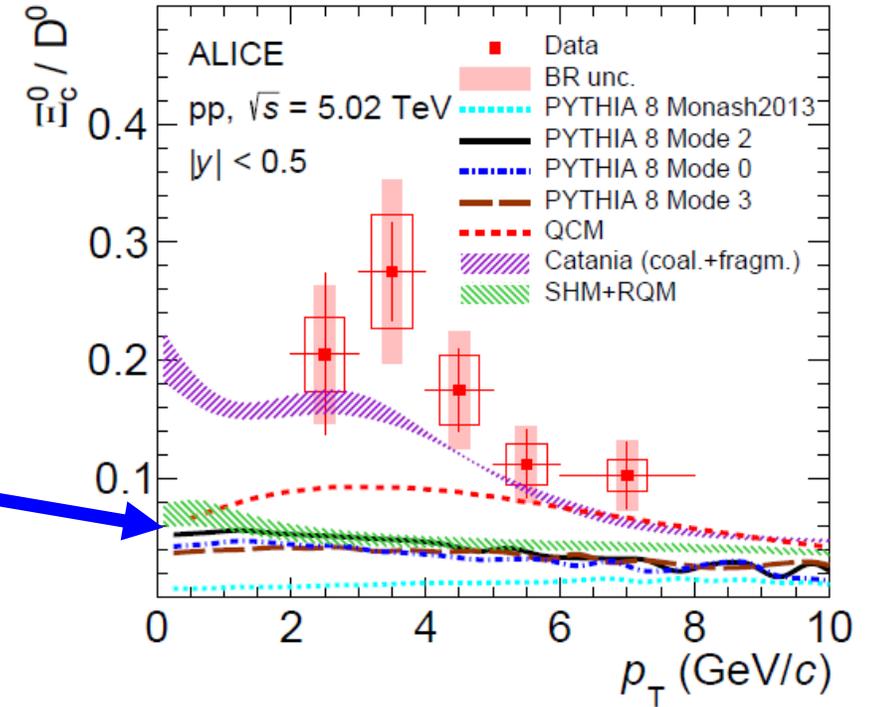

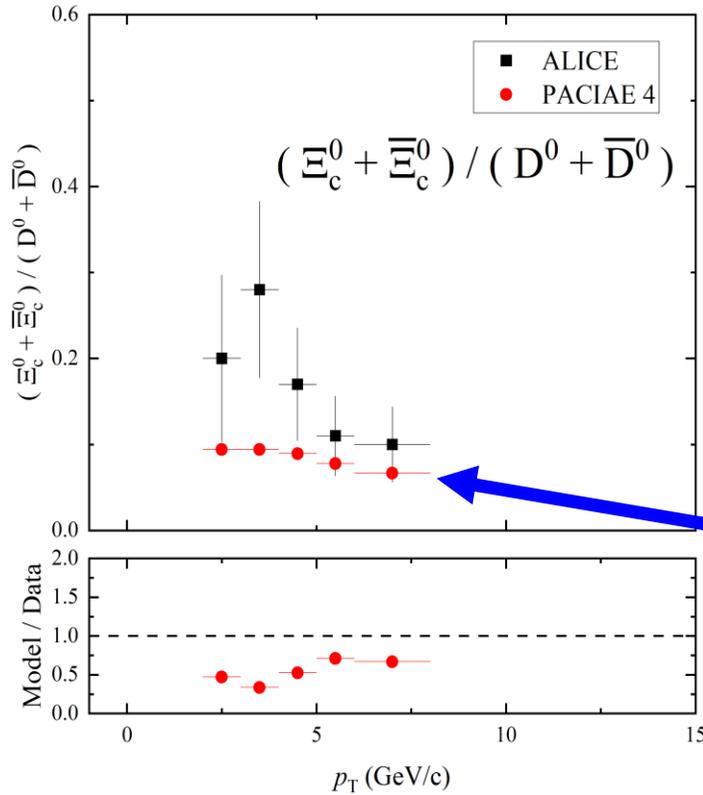

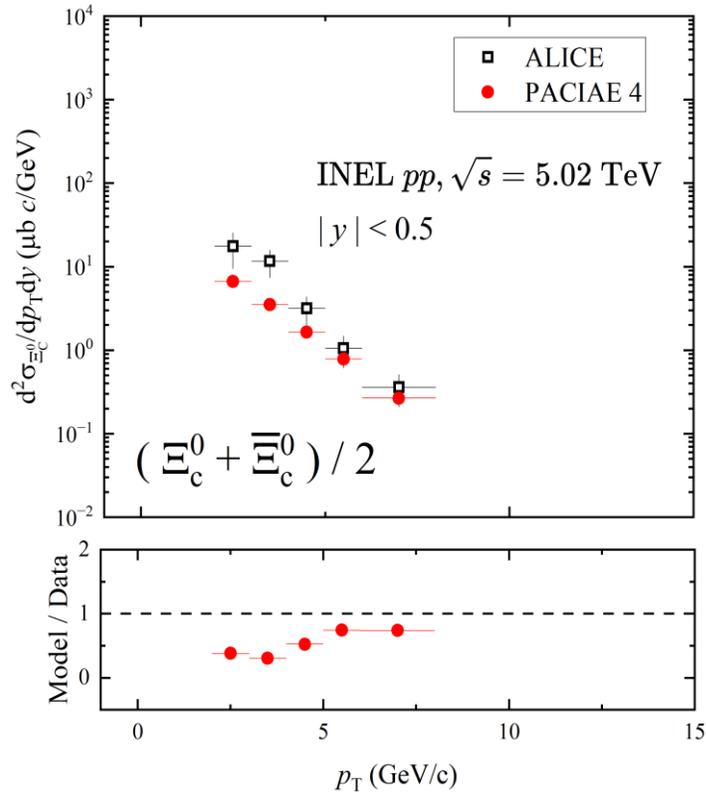

The $c\bar{c}$ production cross sections in PACIAE.

Charm sector

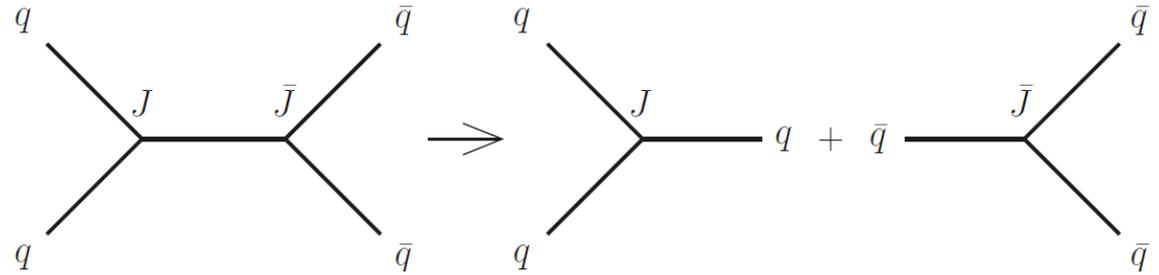

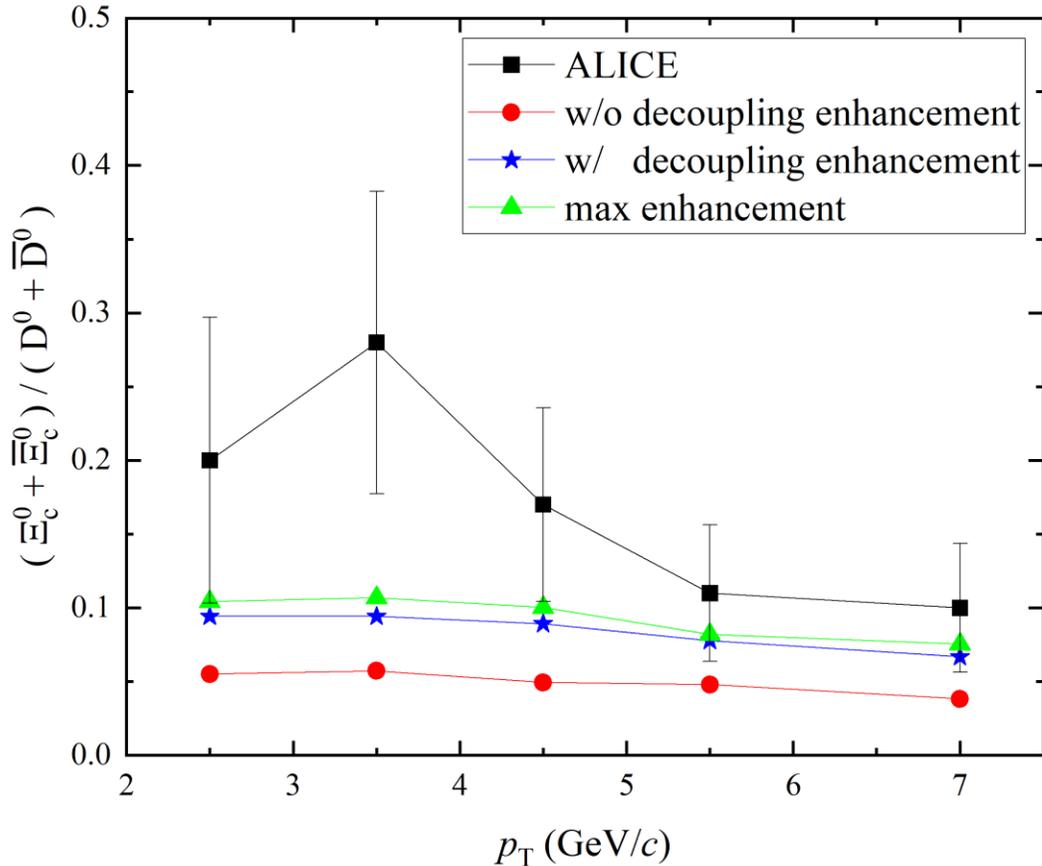

Successfully describe the Λ_c and D^0 data!

Charm sector

Our model enhances Ξ_c . But still underestimate.

Charm sector

Max enhancement: $s\bar{s} : u\bar{u} : d\bar{d} = 1 : 1 : 1$

The decoupling strange enhancement / multiple junction structure?

Summary and outlook

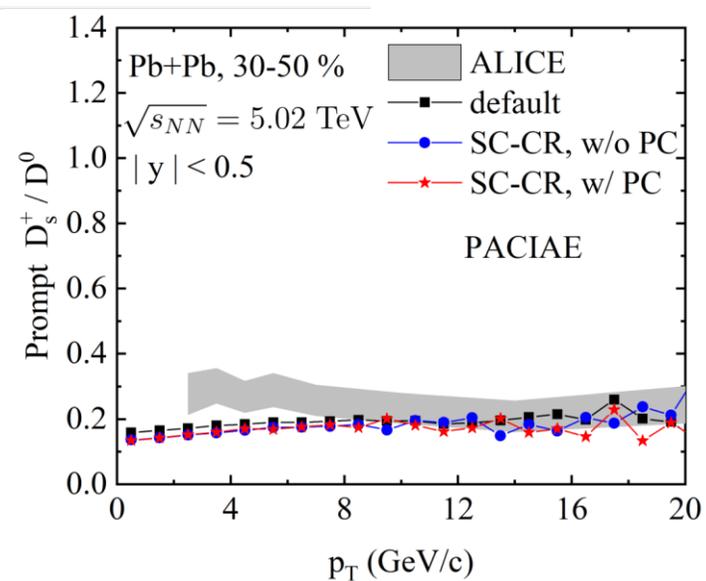

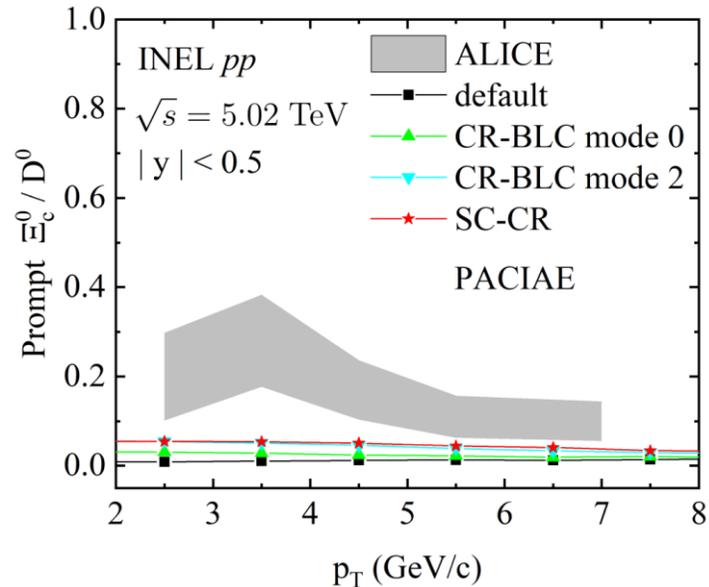

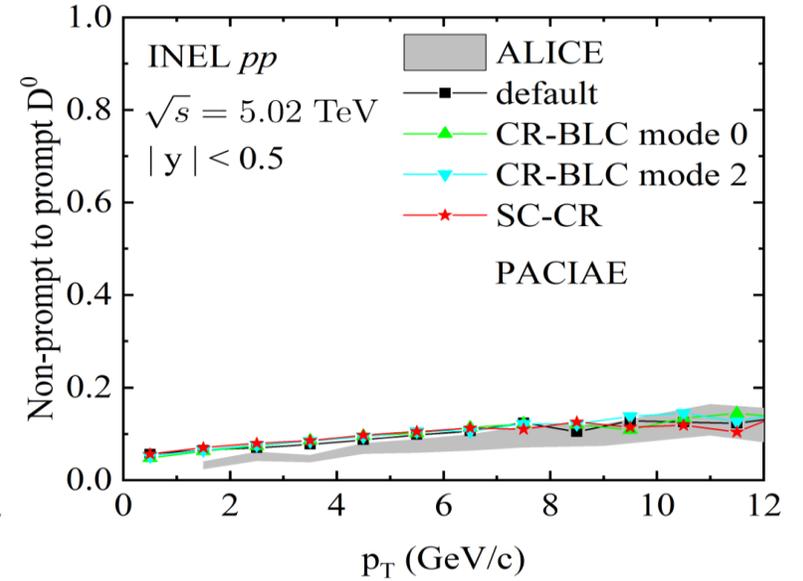

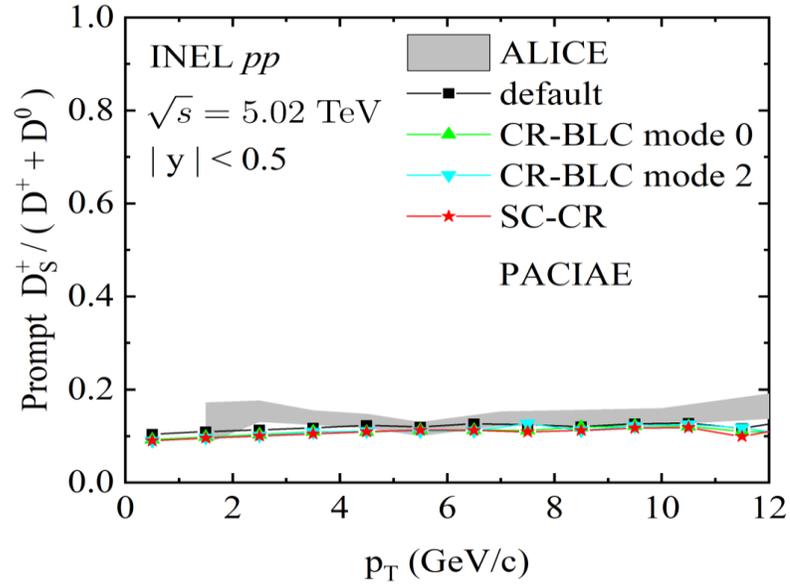

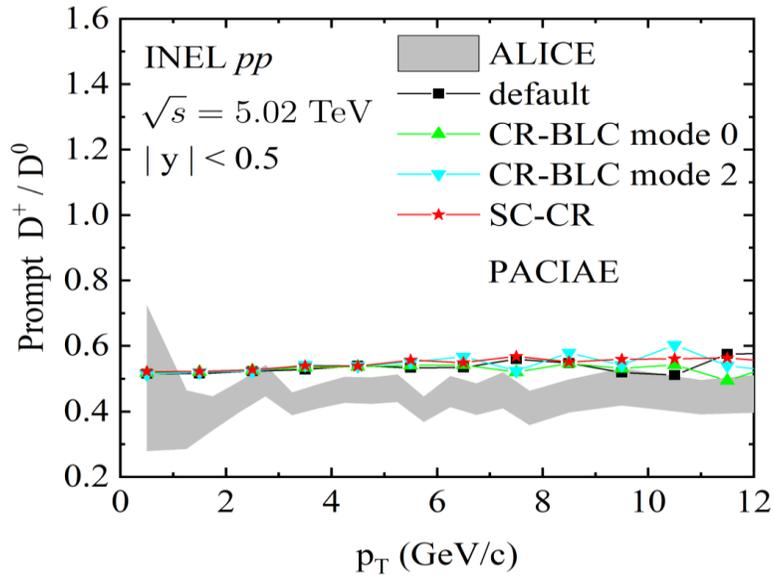

Summary and outlook

1. We introduce a dynamical space-time constrained QCD color reconnection and a junction string tension enhancement mechanism in PACIAE4.
2. With the framework, we successfully describe the p_T spectra and baryon-to-meson ratios of open light and heavy hadrons in pp collisions at $\sqrt{s} = 5.02$ TeV.
3. The production of charm-strange Ξ_c^0 baryons is enhanced in the string fragmentation regime, but still underestimates the experimental data.
3. Multi-junction structures play an essential role in the production of charm baryons.
4. More detailed study for junction structure is required in string phenomenology.
5. From small systems from pp to pA , to large AA ...

Thanks!

PACIAE model: Ver. 4.0

PACIAE: *Parton And-hadron CIAE*

(based on PYTHIA 6 & 8, refactoring and rewriting in modern Fortran + C++)

Beyond-leading color (BLC)

SU(3) color algebra (QCD):

$$3 \otimes \bar{3} = 8 \oplus 1$$

color-triplet quark anti- color-octet gluon color-singlet

More generally:

$$N_c \otimes \bar{N}_c = (N_c^2 - 1) \oplus 1$$

Conversely, in the **LC** limit , the gluon color state (adjoint) can be reduced to the direct product of the quark color state (fundamental) and the antiquark one (antifundamental).
