VII International Symposium on Chiral Symmetry in
Hadrons and Nuclei
Beihang University, Beijing 28 October 2013

Motivation

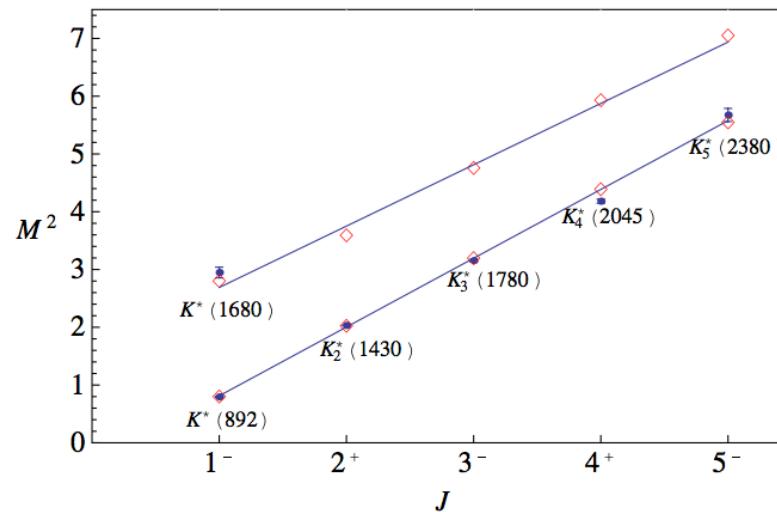

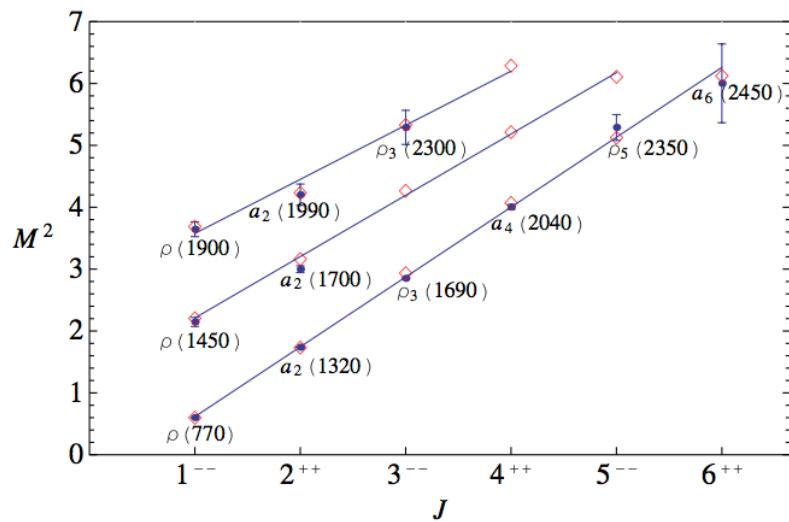

- In S-matrix theory, unitarity in the s channel is the key to determine the properties of resonances and bound states
- Singularities in the complex J -plane (Regge poles) reflect the important contributions of the crossed channels on the direct channel -> contain in principle the most complete description of resonance parameters

In this work we parametrize the Regge poles corresponding to the ρ and σ resonances and fix the parameters by fitting to the experimental data on the physical poles.

Regge trajectories

- **Experimental observation**

Take particles with the same quantum numbers and signature ($\tau=(-1)^J$) and plot (spin) vs. (mass)²

Particles can be classified in **linear trajectories**
with a universal slope

Regge Theory

The Regge trajectories can be understood from the analytic extension to the complex angular momentum plane (Regge Theory)

However, light scalars, particularly the $f_0(500)$, do not fit in

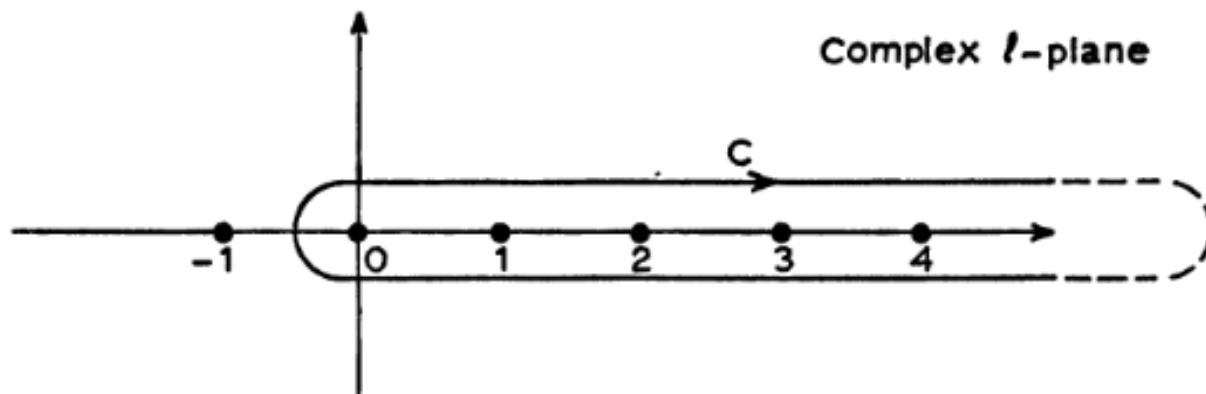

are doubled due to two flavor components, $\bar{n}n$ and $\bar{s}s$. We do not put the enigmatic σ meson [11–14] on the $\bar{q}\bar{q}$ trajectory supposing σ is alien to this classification. The broad state

Regge Theory

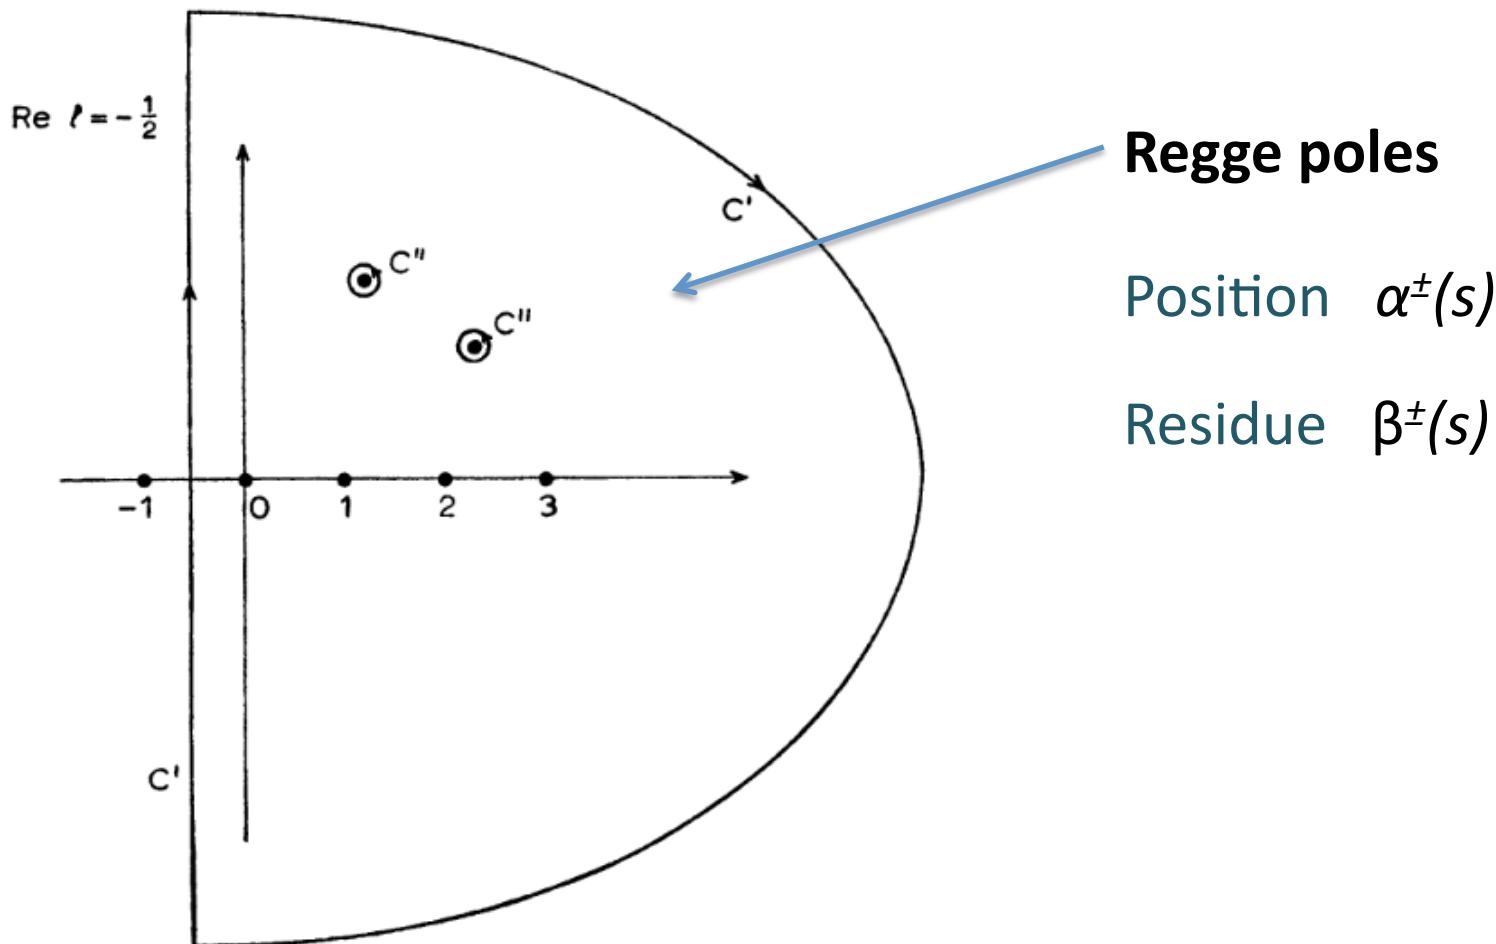

- The concept of partial wave can be expanded to complex values of J , which will be valid in the entire t -plane

Procedure: Sommerfeld-Watson transform

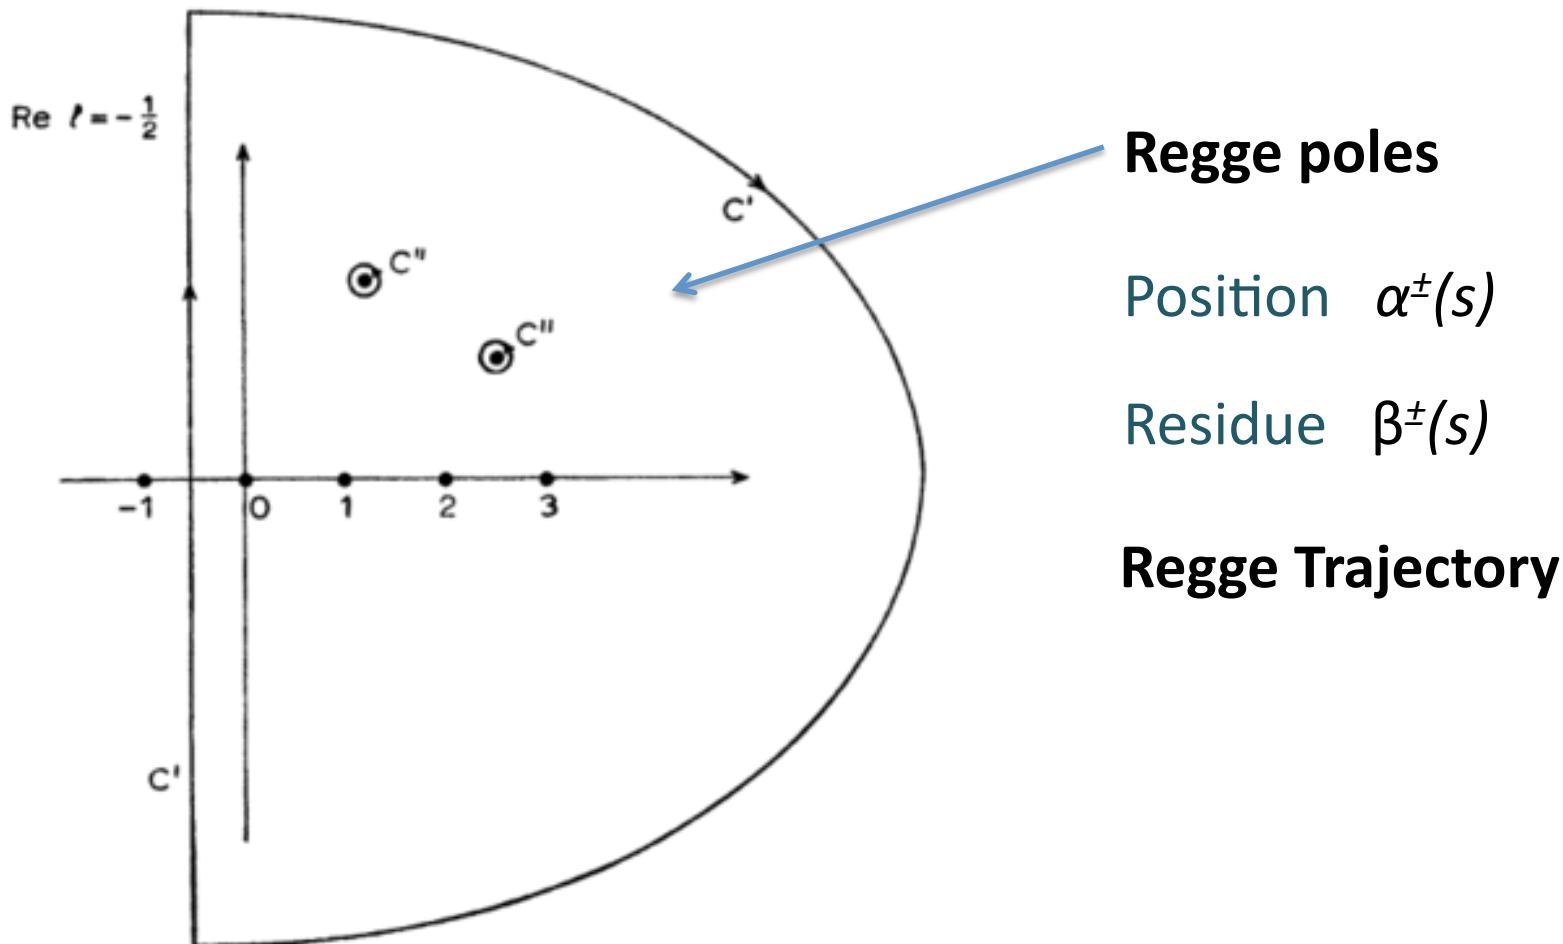

$$T(s, t) = \sum_{J=0}^{\infty} (2J+1) f_J(s) P_J(z) \quad \rightarrow \quad T(s, t) = -\frac{1}{2i} \int_C \frac{(2J+1) f(J, s) P_J(-z)}{\sin \pi J} dJ$$

Regge Theory

Regge Theory

Regge Theory

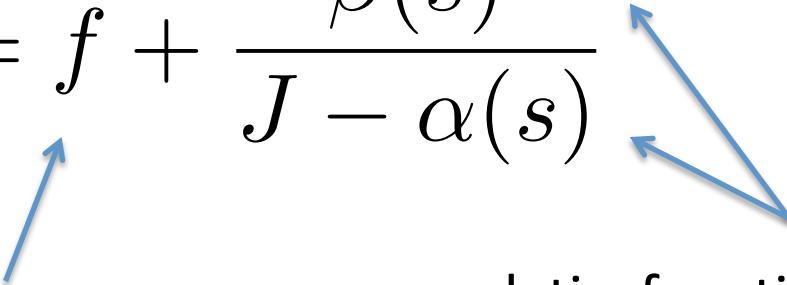

- **Relevance of Regge poles in the s -channel**

Contribution of a single Regge pole to a physical partial wave amplitude

$$f(J, s) = \hat{f} + \frac{\beta(s)}{J - \alpha(s)}$$

regular function

analytic functions
 α : right hand cut $s > 4m^2$
 β : real

Parametrization of the amplitudes

- Unitarity condition on the real axis implies

$$\text{Im } \alpha(s) = \rho(s)\beta(s)$$

- Further properties of $\beta(s)$

$$\beta(s) = \frac{\hat{s}^{\alpha(s)}}{\Gamma(\alpha(s) + \frac{3}{2})} \gamma(s)$$

threshold behavior

$$\hat{s} = \frac{s - 4m^2}{\tilde{s}}$$

suppress poles
of full amplitude

$$(2\alpha + 1)P_\alpha(z_s) \sim \Gamma(\alpha + \frac{3}{2})$$

analytical function:
 $\beta(s)$ real on real axis
 \Rightarrow phase of $\gamma(s)$ known
 \Rightarrow Omnès-type disp. relation

S. -Y. Chu, G. Epstein, P. Kaus, R. C. Slansky and F. Zachariasen, Phys. Rev. 175, 2098 (1968).

Parametrization of the amplitudes

- **Twice-subtracted dispersion relations**

$$\alpha(s) = A + B(s - s_0) + \frac{(s - s_0)^2}{\pi} \int_{\text{thr.}}^{\infty} \frac{\text{Im}\alpha(s')ds'}{(s' - s)(s' - s_0)^2}$$

$$\gamma(s) = g^2 \exp \left\{ C(s - s_0) + \frac{(s - s_0)^2}{\pi} \int_{\text{thr.}}^{\infty} \frac{\phi_{\gamma}(s')}{(s' - s)(s' - s_0)} ds' \right\}$$

with $\beta(s) = \frac{\hat{s}^{\alpha(s)}}{\Gamma(\alpha(s) + \frac{3}{2})} \gamma(s) = \frac{\text{Im}\alpha(s)}{\rho(s)}$

Parametrization of the amplitudes

System of integral equations:

$$\text{Re}\alpha(s) = \alpha_0 + \alpha's + \frac{s}{\pi} PV \int_{4m_\pi^2}^\infty ds' \frac{\text{Im}\alpha(s')}{s'(s' - s)},$$

$$\begin{aligned} \text{Im}\alpha(s) &= \rho(s)b_0 \frac{\hat{s}^{\alpha_0 + \alpha's}}{|\Gamma(\alpha(s) + \frac{3}{2})|} \exp(-\alpha's[1 - \log(\alpha'\tilde{s})]) \\ &+ \frac{s}{\pi} PV \int_{4m_\pi^2}^\infty ds' \frac{\text{Im}\alpha(s') \log \frac{\hat{s}}{\hat{s}'} + \arg \Gamma(\alpha(s') + \frac{3}{2})}{s'(s' - s)} \end{aligned}$$

In the scalar case a slight modification is introduced (Adler zero)

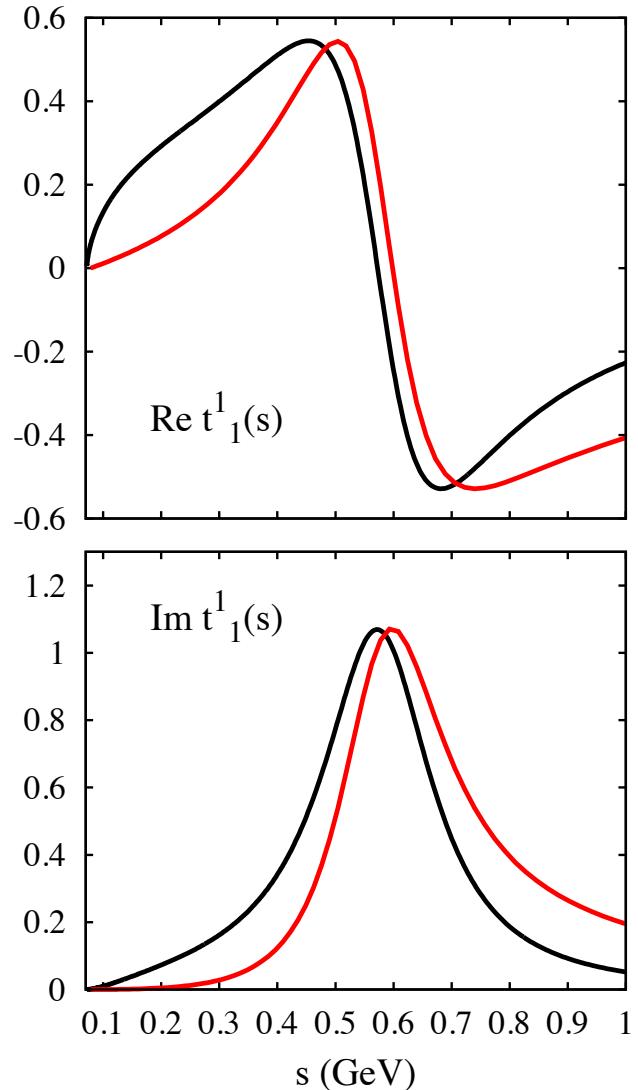

Determination of the parameters

- for a given set of α_0 , α' and b_0 :
 - solve the coupled equations
 - get $\alpha(s)$ and $\beta(s)$ in real axis
 - extend to complex s -plane
 - obtain pole position and residue

$$f^{II}(J, s) = \hat{f} + \frac{\beta(s)}{J - \alpha^{II}(s)}$$

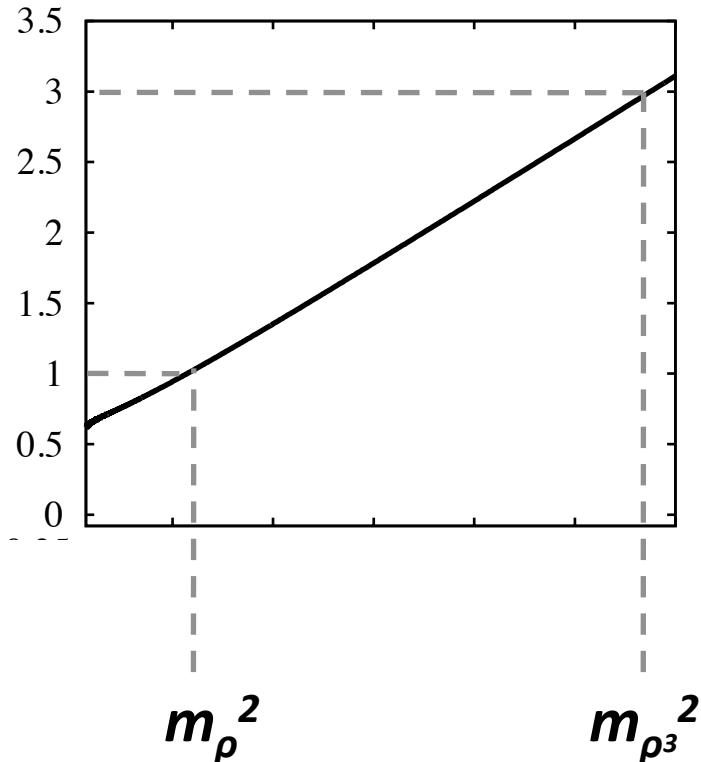

- fit α_0 , α' and b_0 so that **pole position and residue** coincide with those given by a **dispersive analysis of scattering data**

Results: ρ case ($I = 1, J = 1$)

We recover a fair representation of the amplitude, in good agreement with the GKY amplitude

Results: ρ case ($I = 1, J = 1$)

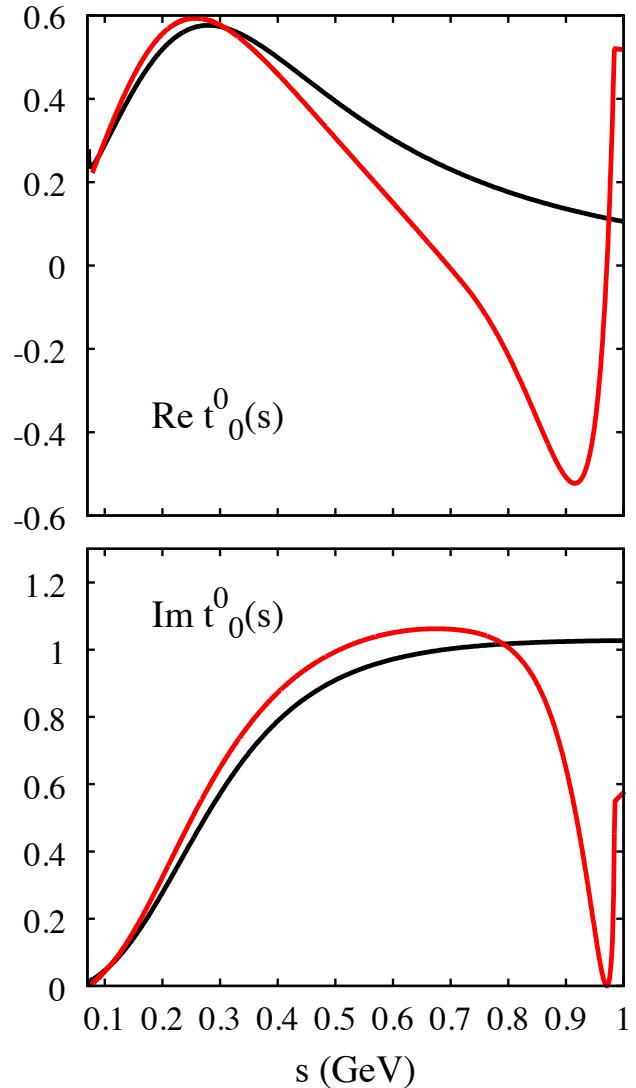

But we also get a prediction for the ρ Regge trajectory, which is:

- $\alpha(s)$ almost real
- almost linear $\alpha(s) \sim \alpha_0 + \alpha' s$
- intercept $\alpha_0 = 0.52$
- slope $\alpha' = 0.913 \text{ GeV}^{-2}$

Remarkably consistent with the literature,
taking into account our approximations

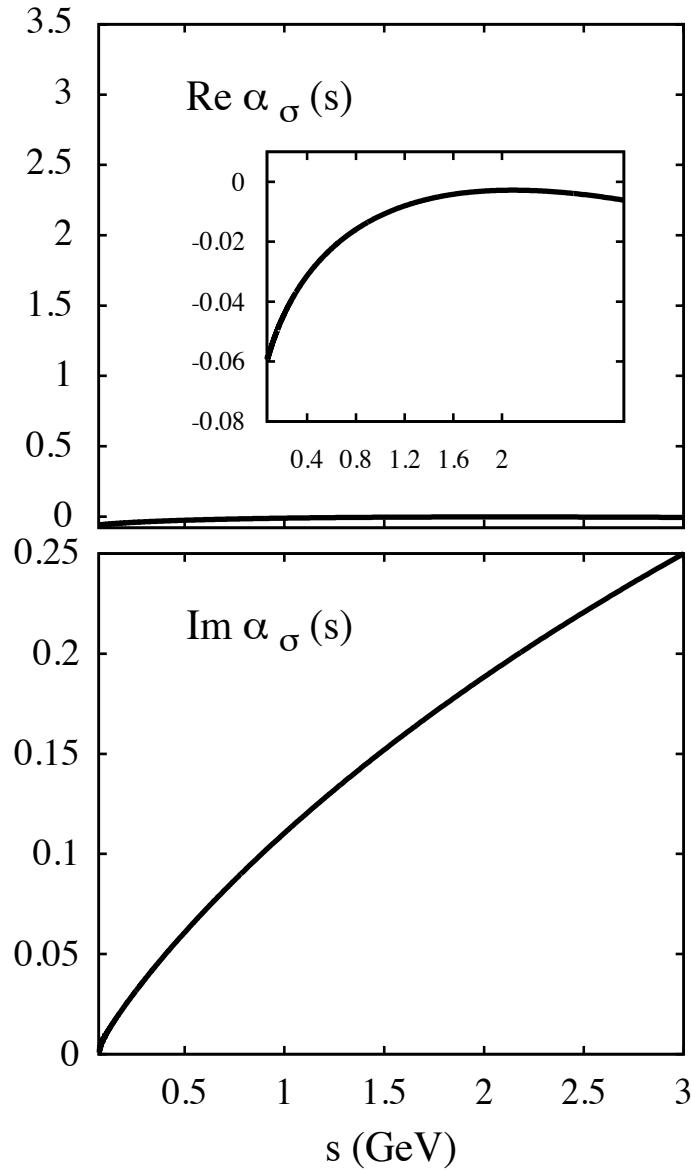

$$m_\rho \rightarrow 0.756 \text{ GeV}; \quad m_{\rho^3} \rightarrow 1.697 \text{ GeV}, \quad \text{PDG: } \rho_3(1690)$$

Results: σ case ($I = 0, J = 0$)

Even better agreement with the parameterized GKY amplitude

Results: σ case ($I = 0, J = 0$)

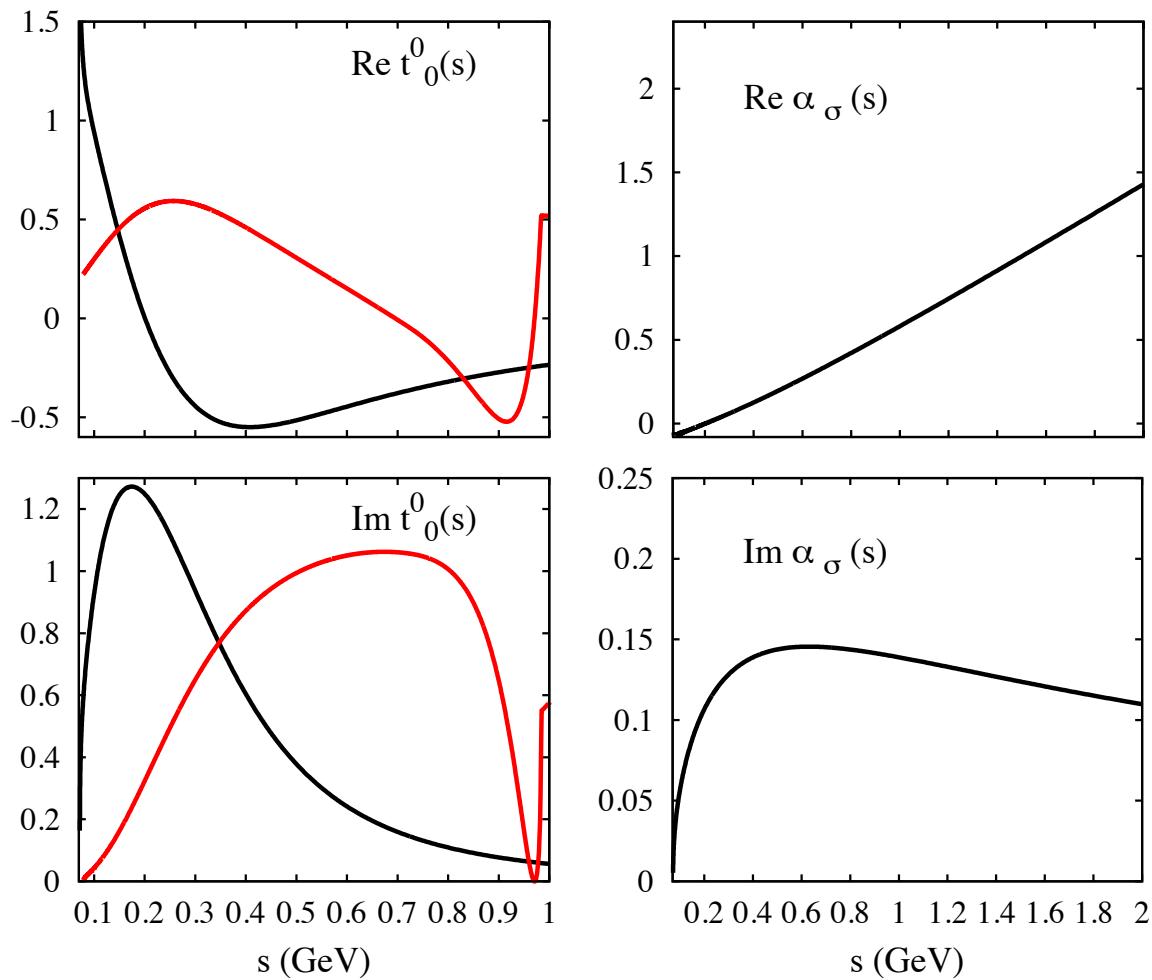

Prediction for the σ Regge trajectory, which is:

- NOT real
- NOT linear
- intercept $\alpha_0 = -0.087$
- slope $\alpha' = 0.002 \text{ GeV}^{-2}$

Two orders of magnitude flatter than other hadrons
The sigma does NOT fit the usual classification

Results: σ case ($I = 0, J = 0$)

If we fix the α' (\sim slope in the “normal” Regge trajectories) to a natural value (that of the ρ trajectory)

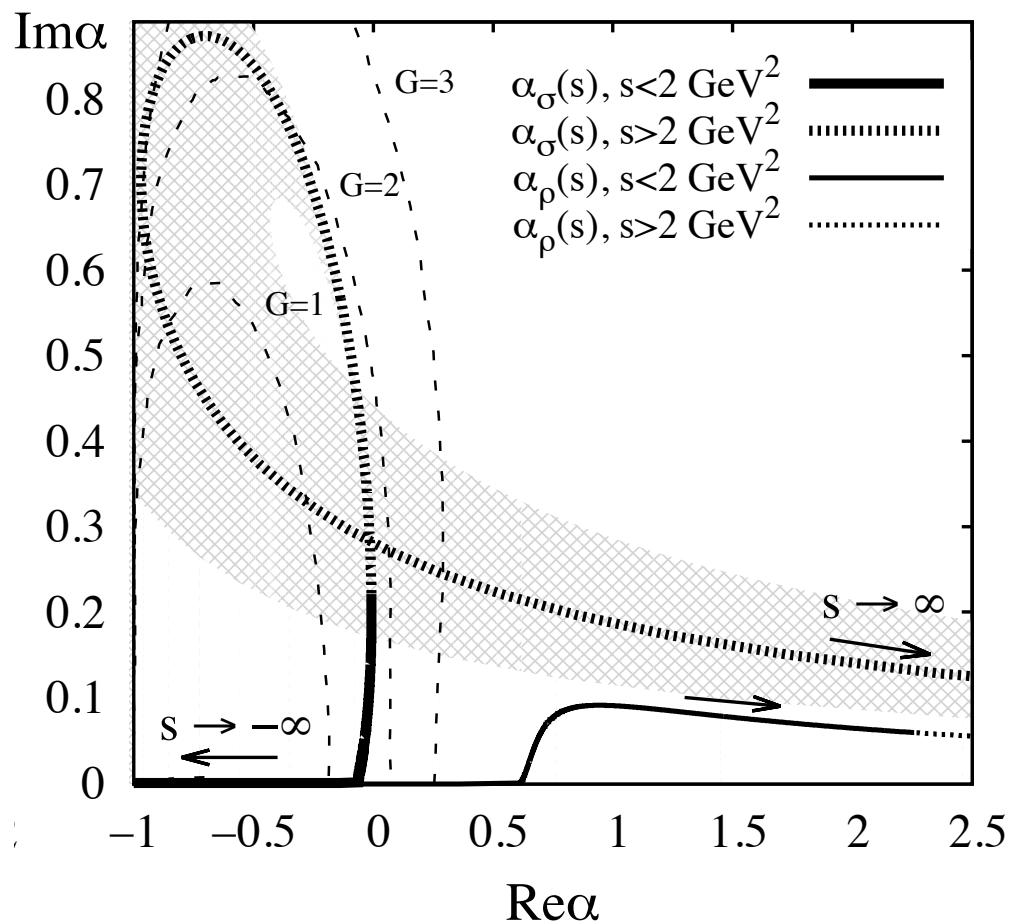

Summary

- We are studying the Regge trajectories that pass through the ρ and σ resonances
- **By fitting to the pole position and residue**, we get the parameters of the Regge parametrization (in particular, the slope of the Regge trajectory)
 - ρ trajectory: parameters consistent with literature
 - σ trajectory: slope of the trajectory **two orders of magnitude smaller than natural**
 - If we force the σ trajectory to have a natural slope, the description of the pole parameters is ruined

Thank you!

Results: comparison to Yukawa potential

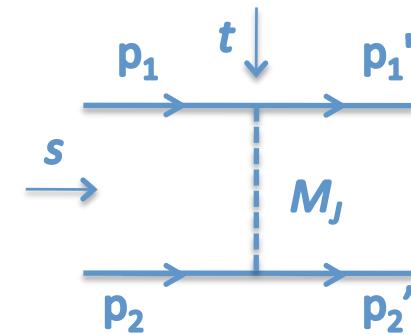

- **Large energy behavior of amplitudes**
 - Froissart bound (amplitude analiticity + unitarity)

$$|T(s, t = 0)| \leq c s (\log s)^2, \quad s \rightarrow \infty$$

- t-channel exchange of a particle of mass M and angular momentum J

$$T(s, t \approx M_J^2) \approx \frac{g^2 P_J(\cos \theta_t)}{M_J^2 - t}$$

Since $\cos \theta_t = 1 + \frac{2s}{t - 4m^2}$, at fixed t and large s

$$P_J(\cos \theta_t) \sim s^J \quad \Rightarrow \quad T(s, t \approx M_J^2) \sim s^J$$

To reconcile both behaviors:

$$\left. \begin{array}{l} |T(s, t = 0)| \leq c s (\log s)^2 \\ T(s, t \approx M_J^2) \sim s^J \end{array} \right\} T(s, t) \sim \beta(t) s^{\alpha(t)}$$

with

$$\alpha(t < 0) < 1 \quad (\text{physical values of } t)$$

$$\alpha(t = M_J^2) = J \quad \text{the Regge trajectory!}$$

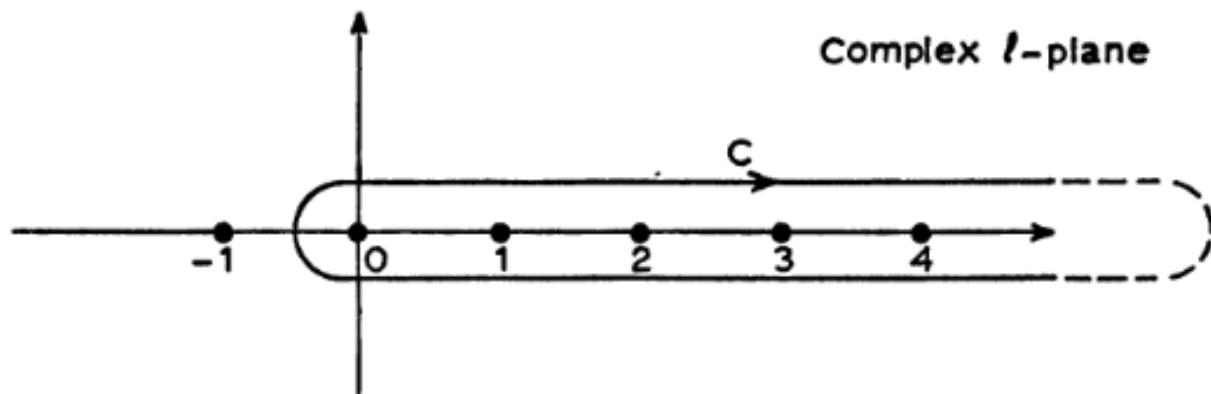

High energy behavior interpreted as an interpolation in J between poles with different spin \rightarrow justifies the continuation of the partial waves to complex values of J

Complex angular momentum

- We want to extend the concept of partial wave to complex values of J , which will be valid in the entire t -plane

Procedure: Sommerfeld-Watson transform

$$T(s, t) = \sum_{J=0}^{\infty} (2J+1) f_J(s) P_J(z) \quad \rightarrow \quad T(s, t) = -\frac{1}{2i} \int_C \frac{(2J+1) f(J, s) P_J(-z)}{\sin \pi J} dJ$$

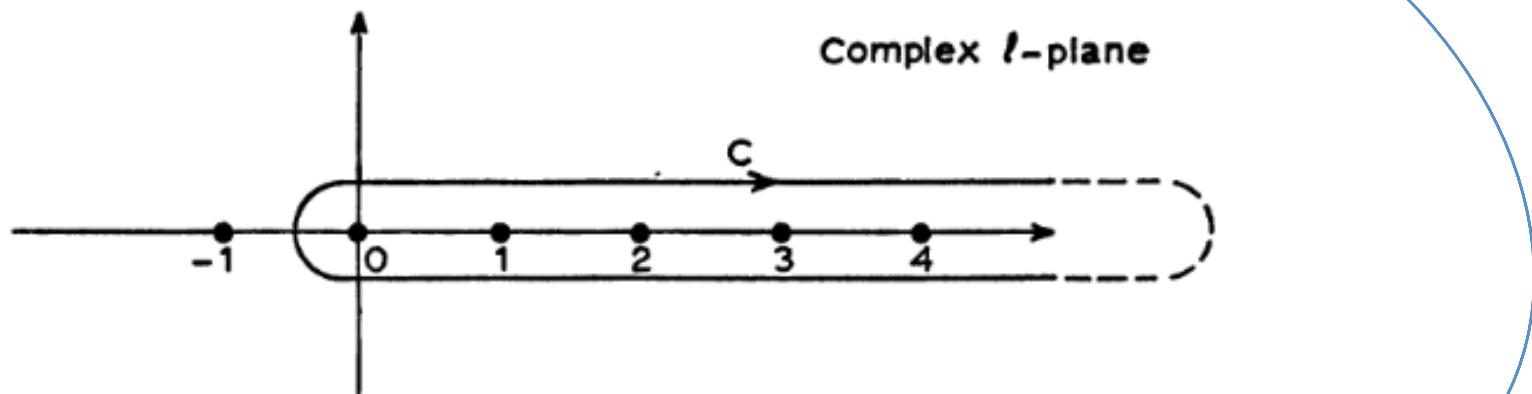

Complex angular momentum

- We want to extend the concept of partial wave to complex values of J , which will be valid in the entire t -plane

Procedure: Sommerfeld-Watson transform

$$T(s, t) = \sum_{J=0}^{\infty} (2J+1) f_J(s) P_J(z) \quad \rightarrow \quad T(s, t) = -\frac{1}{2i} \int_C \frac{(2J+1) f(J, s) P_J(-z)}{\sin \pi J} dJ$$

$$T^\pm(s, t) = -\frac{1}{2i} \int_C \frac{(2J+1) f^\pm(J, s) P_J(-z)}{\sin \pi J} dJ$$

Next step is to deform the contour.

To be sure that it can be done, $f(J,s)$ must have some analytic properties -> we must redefine it:

Froissart-Gribov projection

For J bigger than the number of subtractions that we need to make the integrals converge

$$f^\pm(J, s) = \frac{1}{\pi} \int_{z_0}^{\infty} \{D_t(s, z) \pm D_u(s, z)\} Q_J(z) dz$$

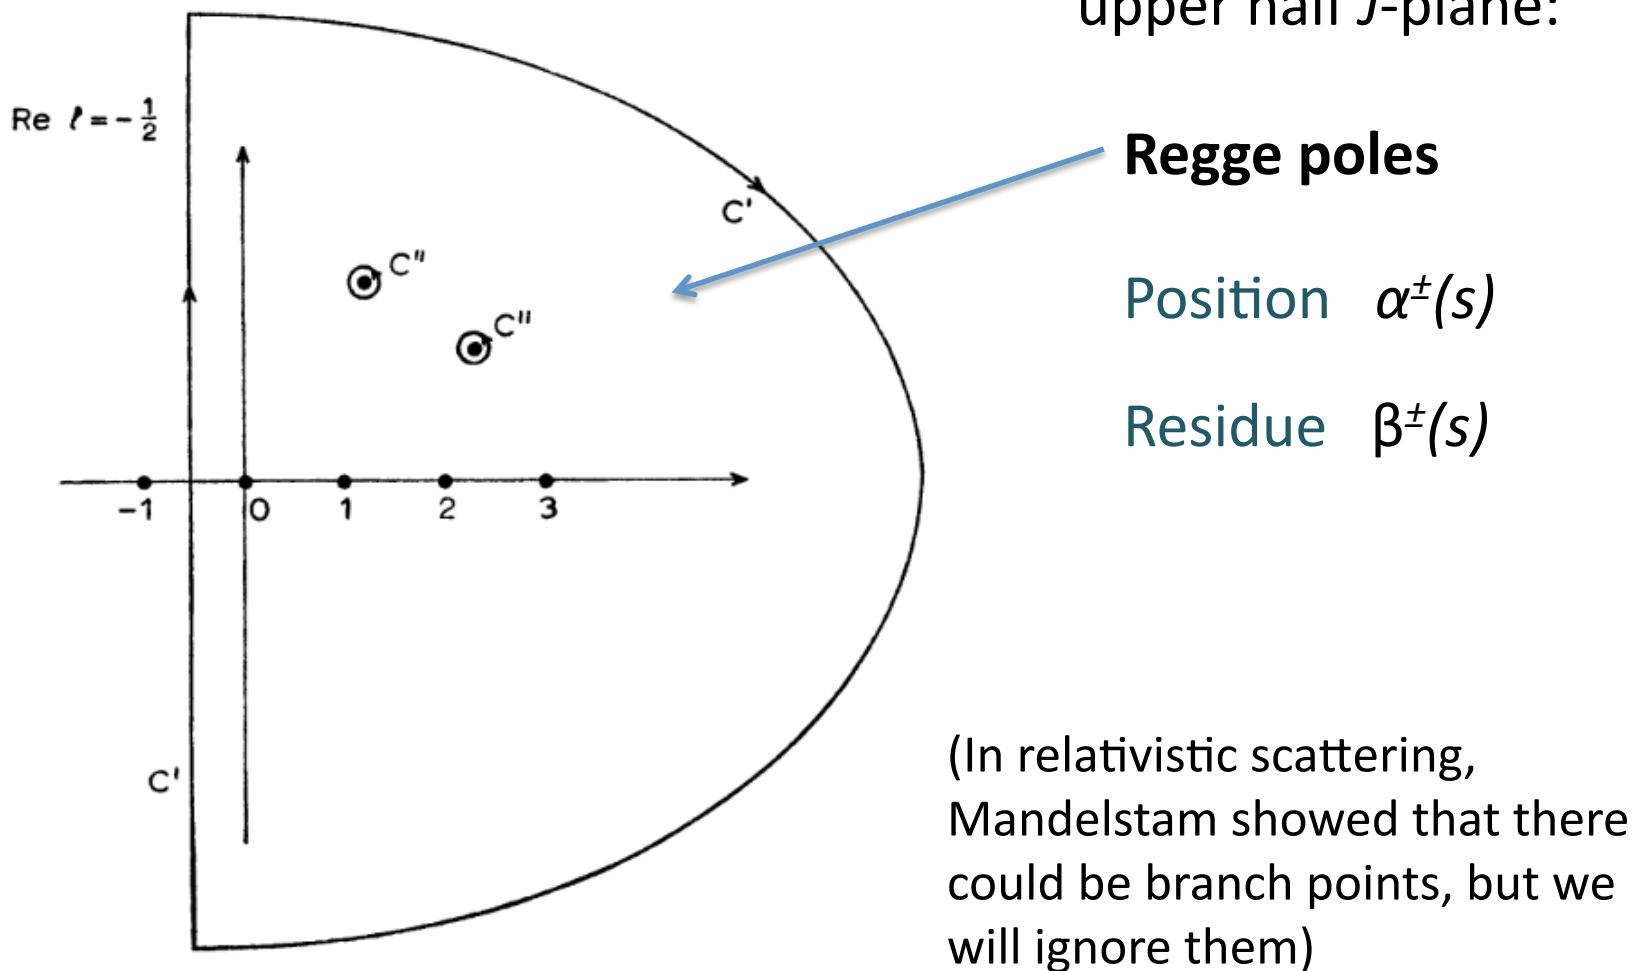

$$f_J(s) = f^+(J, s) \quad \text{for even } J$$

$$f_J(s) = f^-(J, s) \quad \text{for odd } J$$

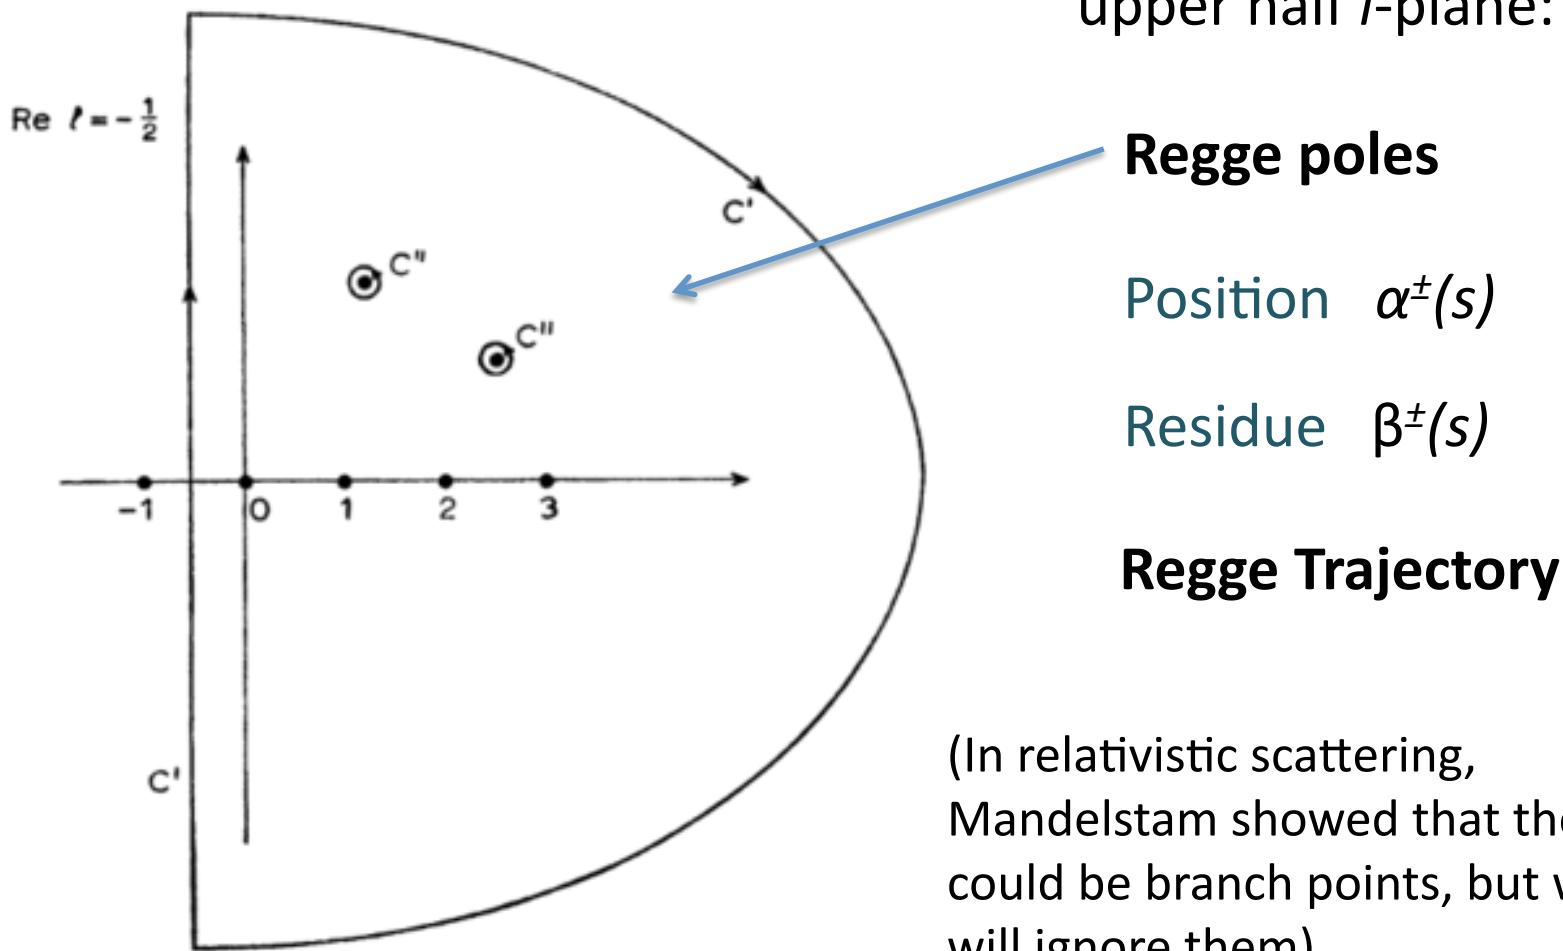

Associated $T^\pm(s,z)$ such that

$$T(s, z) = \frac{1}{2} \{T^+(s, z) + T^+(s, -z) + T^-(s, z) - T^-(s, -z)\}$$

In non-relativistic scattering, Regge found that the only singularities of $f^\pm(J,s)$ in the region $\text{Re } J > -\frac{1}{2}$ are poles in the upper half J -plane:

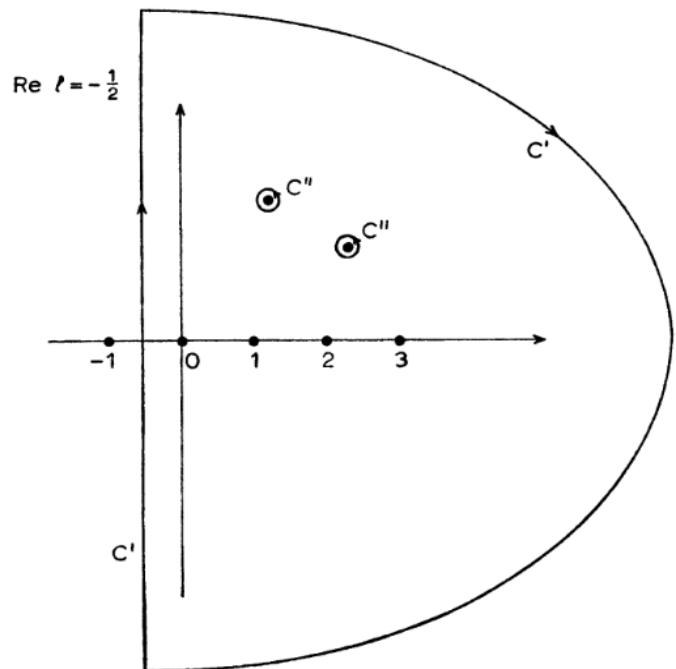

In non-relativistic scattering, Regge found that the only singularities of $f^\pm(J,s)$ in the region $\text{Re } J > -\frac{1}{2}$ are poles in the upper half J -plane:

Integration on the contour →

$$T^\pm(s, z) = -\frac{1}{2i} \int_{C'} \frac{(2J+1)f^\pm(J, s)P_J(-z)}{\sin \pi J} dJ - \sum_i \frac{\pi(2\alpha_i^\pm(s)+1)\beta_i^\pm(s)P_{\alpha_i^\pm}(-z)}{\sin \pi\alpha_i^\pm(s)}$$

Background term

$$T^{\text{poles}}(s, t) =$$

$$-\sum_i \frac{\pi(2\alpha_i^\pm(s)+1)}{2 \sin \pi\alpha_i^\pm} \beta_i^\pm(s) (P_{\alpha_i^\pm}(-z) \pm P_{\alpha_i^\pm}(z))$$

$\alpha^+(s)$ only contribute to the amplitude when the trajectory passes through even integer values (and viceversa)

- **Relevance of Regge poles in the s -channel**

Contribution of a single Regge pole to a physical partial wave amplitude

$$f_l^{\text{pole}}(s) = \frac{1}{2} \int_{-1}^1 P_l(z) T^{\text{pole}}(s, t) dz = -\frac{1}{2}(1 \pm (-1)^l)\beta(s) \frac{2\alpha(s) + 1}{(\alpha(s) - l)(\alpha(s) + l + 1)}$$

even signature poles only contribute to *even* pw amplitudes

Near the Regge pole:

$$f_l(s) = \hat{f}_l + \frac{\beta(s)}{l - \alpha(s)}$$

regular function

 
 analytic functions
 α : right hand cut $s > 4m^2$
 β : real

- **Relevance of Regge poles in the t -channel**

Assymptotic behavior of $P_\alpha(z)$ when $z \rightarrow \infty$ ($t \rightarrow \infty$)

$$\sqrt{\pi}P_\alpha(z) \sim \frac{(\alpha - \frac{1}{2})!}{\alpha!} (2z)^\alpha + \frac{(-\alpha - \frac{3}{2})!}{(-\alpha - 1)!} (2z)^{-\alpha-1}$$

Dominated by leading Regge pole (largest $\operatorname{Re} \alpha$)

$$T(s, t) \sim \phi(s)t^{\alpha(s)}$$

- **Relevance of Regge poles in the s -channel (cont.)**

The whole family of resonances in the Regge trajectory (with spins spaced by two units) contributes to the amplitude
