

# KAGRA

## Underground Cryogenic Gravitational Wave Telescope

S. Haino, Academia Sinica  
KAGRA collaboration

# Gravitational waves (GW)

- Predicted by A. Einstein in 1916

Ripple of space-time propagating in speed of light

GW is transparent for any material,  
except gravity sources.

This causes detection to be difficult,  
while it can bring us information  
from where we wouldn't see by EM

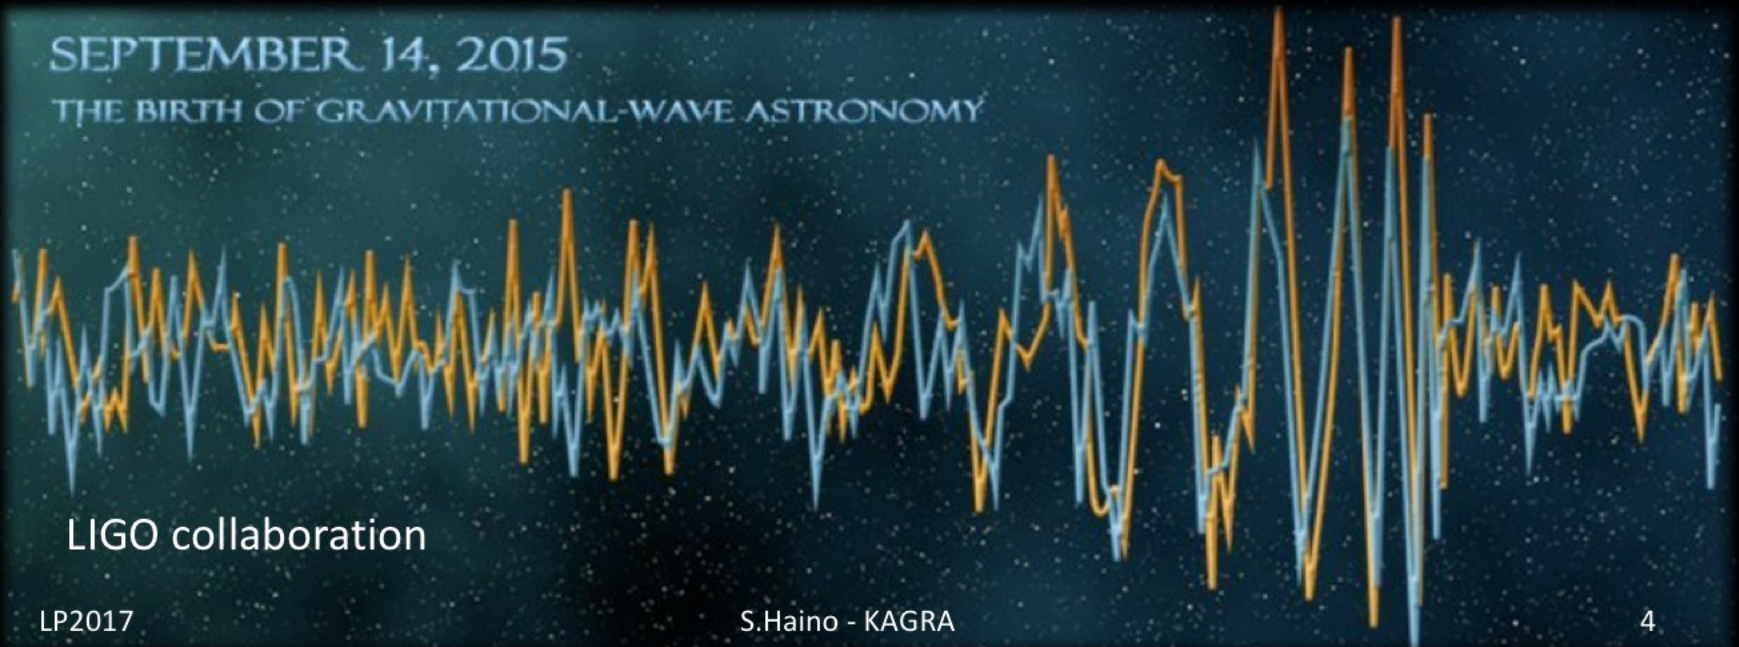

# Gravitational waves (GW)

- Predicted by A. Einstein in 1915
- Laser interferometer was developed to detect GW

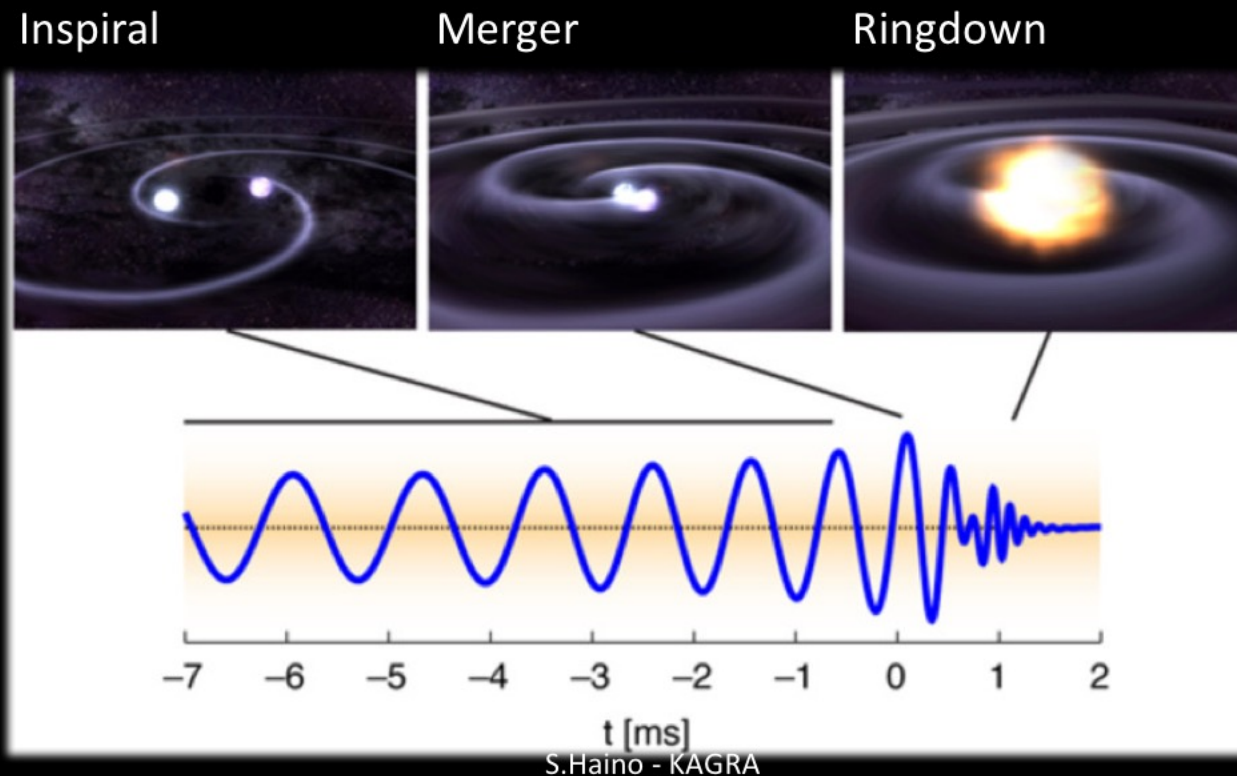

# Gravitational waves (GW)

- Predicted by A. Einstein in 1915
- First detection by LIGO in 2015 !!

# GW sources and physics

- Compact Binary Coalescences  
Black Holes (BH) and/or Neutron Stars (NS)

# GW sources and physics

- Compact Binary Coalescences  
Physics examples

- Test of General Relativity
- Possible progenitor of Gamma-Ray Burst (GBR)
- Determination of cosmological parameters with GW “Standard siren”  $\Leftrightarrow$  EM “standard candle”

*\*Possibly neutron stars.*

# GW sources and physics

- Compact Binary Coalescences

- Continuous waves from pulsars

- Supernovae

- Stochastic GW background from Early Universe

# GW sources and physics

from Early Universe

# Typical GW strain amplitude

$$h \sim \frac{2G}{c^4 R} \ddot{I} \sim \frac{2G}{c^4 R} \frac{Mr^2}{T^2} \sim \frac{2GM}{c^2} \frac{1}{R} = \frac{r_g}{R}$$

The diagram illustrates the derivation of the typical GW strain amplitude formula. The formula is broken down into three parts, each enclosed in a blue box with an arrow pointing to its corresponding term in the equation above:

- The first box contains  $\sim Mc^2$ , which points to the  $\frac{2GM}{c^2}$  term in the equation.
- The second box contains  $r_g$  and "Schwarzschild radius", which points to the  $\frac{2GM}{c^2}$  term in the equation.
- The third box contains  $R$  and "Distance", which points to the  $\frac{1}{R}$  term in the equation.

# Typical GW strain amplitude

$$h \sim \frac{2G}{c^4 R} \ddot{I} \sim \frac{2G}{c^4 R} \frac{Mr^2}{T^2} \sim \frac{2GM}{c^2} \frac{1}{R} = \frac{r_g}{R}$$

e.g. Solar mass ( $r_g \sim 3\text{km}$ ) NS-NS binary merging at  $\sim$ speed of light located at 100 Mpc away

$$h \sim \frac{3 \text{ km}}{100 \text{ Mpc}} = 10^{-21}$$

GW signal is very tiny but propagate as  $1/R$  (not  $1/R^2$ )

# Opening of GW astronomy

- LIGO's GW detection opened a new era
- GW amplitude is proportional to  $1/\text{Distance}$
- 10 times improvement of sensitivity will increase number of sources by 1000 !

# World-wide GW detector network

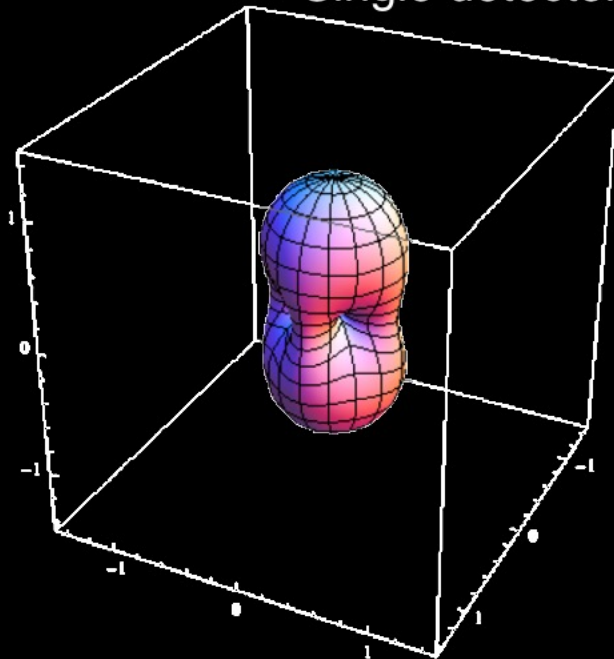

# Advantages of detector network

- Increase the sky coverage

Single detector

LIGOx2 +VIRGO +KAGRA

# Advantages of detector network

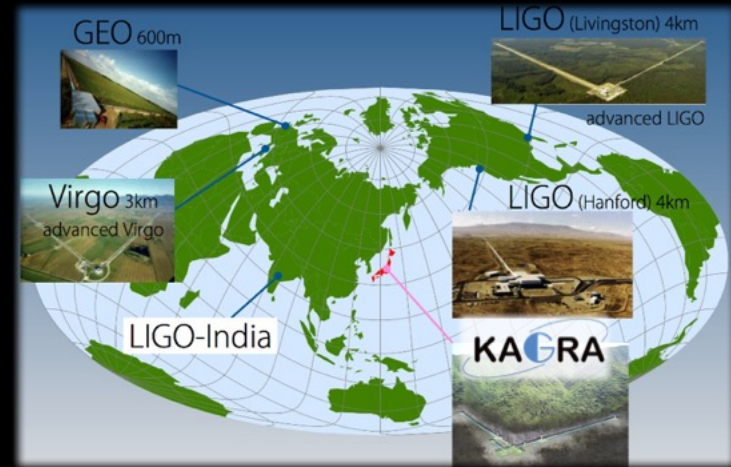

- Increase the sky coverage
- Improve the source localization

GW events locations  
by only 2 LIGO detectors

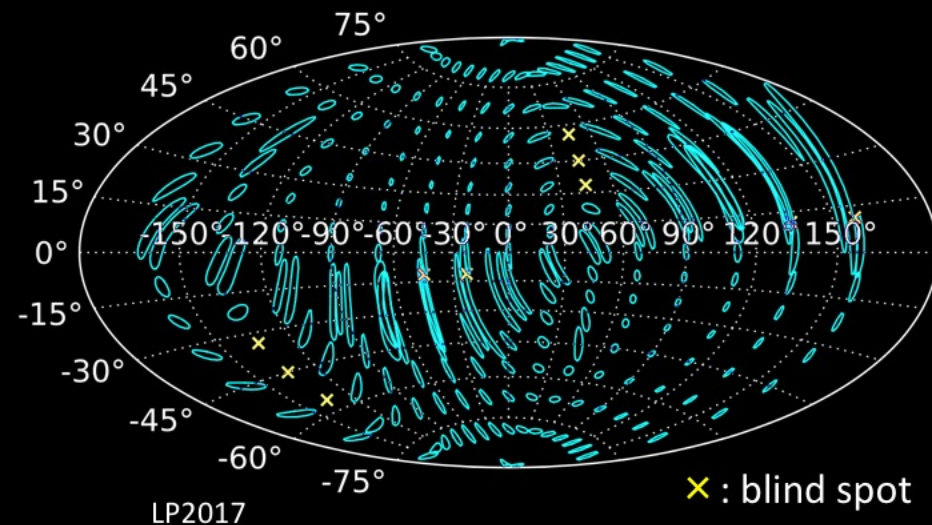

# Advantages of detector network

- Increase the sky coverage
- Improve the source localization

# Vacuum System

- In order to minimize the laser scattering noise ultra-high vacuum ( $10^{-7}$  Pa) is required
- GW detectors are the three world largest vacuum system
  - LIGO  $1.2\text{m}\phi \times 4\text{km} \times 2 = 10,000 \text{ m}^3$  (each)
  - Virgo  $1.2\text{m}\phi \times 3\text{km} \times 2 = 6,800 \text{ m}^3$
  - KAGRA  $0.8\text{m}\phi \times 4\text{km} \times 2 = 3,000 \text{ m}^3$
  - LHC  $110 \text{ m}^3$

# Observation Scenario

- With 25-40 Mpc in 2020, 40-140 Mpc in 2021

Living Reviews in Relativity 19, 1 (2016)  
to be updated

# Summary

- GW will allow us to explore new physics and early Universe
- The next milestone is to build world wide network
- KAGRA is the first km-scale GW detector at underground and with cryogenic mirrors based on many particle accelerator technologies
- We expect to have physics results around ~2020
