Probing gluon saturation

- Gluon recombination at small-*x* → Glauon Saturation [Gribov, Levin, Ryskin (1983)][Mueller, Qiu(1986)]
- NONLINEAR Balitsky-Kovchegov equation descries *x*-evolution of gluon distribution. [Balitsky(1996), Kovchegov(1996)]
- A def of Saturation scale

$$Q_{s,A}^2(x) = \frac{\alpha_s N_c}{S_{A\perp}} x G_A(x) \sim A^{1/3} \left(\frac{1}{x}\right)^{0.3}$$

- $Q > Q_s$: the dilute regime in which collinear factorization is applicable.
- $Q < Q_s$: the dense regime \Rightarrow the Color-Glass-Condensate (CGC) framework

◆□ ▶ ◆□ ▶ ◆ 三 ▶ ◆ 三 ■ ■ つくぐ

Forward onium production in p+A collisions

- Onium $(J/\psi, \psi(2S))$ production in p+A collisions at RHIC and the LHC provides unique playground to study gluon saturation or test the CGC framework.
 - $\checkmark c\bar{c}$ is largely produced via initial gluon fusion.
 - \checkmark The largest saturation scale for nuclei at the energy frontier : $m_c < Q_{sA}$
- The CGC can be helpful in understanding of Onium production mechanism at low-P₁
- Gluon saturation is Cold Nuclear Matter (CNM) effect. \rightarrow Baseline for A+A collisions
- e+A at JLab or BNL : Not yet, but promising! p+A can be complementary to e+A.

J/ψ production in the CGC + NRQCD

[Kang, Ma, Venugopalan (2013)][Ma, Venugopalan (2014)][Ma, Venugopalan, Zhang (2015)]

• The CGC cross sections at short distance are matched to NRQCD LDMEs.

$$d\sigma_{pA}^{H} = \sum_{\kappa} \underbrace{d\hat{\sigma}_{pA}^{\kappa}}_{\text{CGC}} \times \underbrace{\langle O_{\kappa}^{H} \rangle}_{\text{LDMEs}}$$

• Overlap region between the CGC and the NLO collinear factorization : $P_{\perp} \sim 5$ GeV.

• The contribution of CS channel is relatively small. (10% in pp, 15% – 20% in pA at small- P_{\perp}) \implies CEM works qualitatively.

Kazuhiro Watanabe (ODU)

$\psi(2S)$ production : A puzzle

- $c\bar{c}$ produced at short distance $t_c \gtrsim 1/2m \sim 0.07$ fm does not know yet long distance information.
- The saturation effect is short distance physics at t_c and $M_{J/\psi} \sim M_{\psi(2S)} \Rightarrow$ The CGC frameowork predicts $R_{pA}^{J/\psi} \sim R_{pA}^{\psi(2S)}$.
- The large suppression of $\psi(2S)$ production in p+A at both RHIC and the LHC has widely been interpreted as arising from final state interactions with hadron comovers. see [Ferreiro (2015)]
- We shall argue this from an aspect of factorization breaking effect in the Onium formation.

Factorization breaking effect

- In the very forward rapidity region, bound state formation can happen far outside of nucleus. [Sun, Qiu, Xiao, Yuan (2013)]
- However, must be careful at low P_{\perp} because soft color exchanges between spectators and $c\bar{c}$ pair is indispensable. \implies Breaking of factorization [Brodsky, Mueller (1988)]

• Indeed, soft color exchanges between partonic comovers and the $c\bar{c}$ can affect greatly $\psi(2S)$ production. \Longrightarrow The strong nuclear suppression of $\psi(2S)$ at the LHC. (Later)

Next : We examine how the factorization breaking effect with soft color exchange affects J/ψ and $\psi(2S)$ production.

< ロ > < 同 > < 回 > < 回 >

Onia production in the CGC + Improved CEM

- Description of $\psi(2S)$ production is not clear in the CGC+NRQCD. Large uncertainties in association with charm mass and LDMEs. See [Ma, Venugopalan (2014)]
- We employ an Improved version of CEM (ICEM). [Ma, Vogt (2016)], See also Vogt's talk (Wed.)
 - The CGC+CEM is consistent with the CGC+NRQCD in the sense that color octet $c\bar{c}$ is mainly considered.
 - ICEM can reproduce different P_{\perp} distributions of J/ψ and $\psi(2S)$ correctly.

$$\frac{d\sigma_{\psi}}{d^2 P_{\perp} dy} = F_{q\bar{q} \to \psi} \int_{m_{\psi}}^{2m_Q} dM \left(\frac{M}{m_{\psi}}\right)^2 \frac{d\sigma_{q\bar{q}}}{dM d^2 P'_{\perp} dy} \bigg|_{P'_{\perp} = \frac{M}{m_{\psi}} P_{\perp}}$$

where

$$\frac{d\hat{\sigma}_{q\bar{q}}}{d^2q_{\perp}d^2p_{\perp}dy_q dy_p} = \frac{\alpha_s^2}{64\pi^6 C_F} \int \frac{d^2k_{2\perp}d^2k_{\perp}}{(2\pi)^4} \frac{\Xi(k_{1\perp},k_{2\perp},k_{\perp})}{k_{1\perp}^2k_{2\perp}^2} \,\varphi_{\mathsf{p},x_1}(k_{1\perp}) \,\phi_{A,x_2}(k_{2\perp},k_{\perp}) \,.$$

with

$$\begin{split} \varphi_{\mathrm{p},x}(k_{1\perp}) &= \pi R_{\mathrm{p}}^2 \, \frac{N_c \, k_{1\perp}^2}{4\alpha_s} \, \int \, \frac{d^2 l_\perp}{(2\pi)^2} F_x(k_\perp - l_\perp) F_x(l_\perp) \\ \phi_{\mathrm{A},x}(k_{2\perp}) &= \pi R_{\mathrm{A}}^2 \, \frac{N_c \, k_{2\perp}^2}{4\alpha_s} F_x(k_{2\perp} - k_\perp) F_x(k_\perp) \end{split}$$

Rapidity dependence of the dipole amplitude F_x follows the running coupling BK eq. $\exists x \in A \cup A$

• m = 1.3 GeV, fixed coupling $\alpha_s(Q_0)$

- Matching between φ and CTEQ6M at x = 0.01 gives R_p ~ 0.43 fm, Q₀ ~ 8.1 GeV. R_A is chosen to reproduce R_{pA} = 1 when p_⊥ → ∞.
- Initial saturation scales : $Q_{sp,0}^2$ is chosen as MV model, $Q_{sA,0}^2 = (1.5 2)Q_{sp,0}^2$.
- φ at large-*x* (forward rapidity) : matching to collinear PDF *xG* and switch from φ to *xG* at $x = x_0$.
- In p+p collisions, $F_{q\bar{q}\to\psi}$ is fitted and should include the effect of soft color exchanges at final stage.
- Important assumption : the role of soft color exchanges should be enhanced in p+A collisions. → Λ is responsible for the nuclear enhancement effect.

$$\frac{d\sigma_{\psi}}{d^2 P_{\perp} dy} = F_{q\bar{q} \to \psi} \int_{m_{\psi}}^{2m_Q - \Lambda} dM \left(\frac{M}{m_{\psi}}\right)^2 \left. \frac{d\sigma_{q\bar{q}}}{dM d^2 P'_{\perp} dy} \right|_{P'_{\perp} = \frac{M}{m_{\psi}} P_{\perp}}$$

where Λ denotes the average momentum kick given by additional nuclear parton comovers.
For simplicity, we assume that Λ is independent of P_⊥ and y.

P_{\perp} spectra of J/ψ and $\psi(2S)$ in p+p/p+A

Kazuhiro Watanabe (ODU)

Why does Λ so affect $\psi(2S)$ yield?

- The fact that $\psi(2S)$ is more massive object is not important.
- The phase space of the produced $c\bar{c}$ pair is limited to lie within the narrow range for $\psi(2S)$. For J/ψ production, the $c\bar{c}$ pair has a significantly larger phase space.
- Indeed, $\Delta E_{\psi(2S)} = 2m_D m_{\psi(2S)} \sim 50 \text{ MeV}, \Delta E_{J/\psi} = 2m_D m_{J/\psi} \sim 650 \text{ MeV}.$
- Additional soft color exchanges in p+A collisions can break up the $\psi(2S)$ by providing the energy to push the bound Onia over the $D\bar{D}$ decay threshold.

[Ma, Venugopalan, KW, Zhang (2017)]

- The factorization breaking effect clearly leads to a stronger $\psi(2S)$ suppression while it is negligible for J/ψ .
- The enhanced soft color exchanges in p+A are sufficient to explain the data.

= 200

(日)

Double ratio

[Ma, Venugopalan, KW, Zhang (2017)]

- Advantage of the double ratio : many systematic uncertainties including Q_{sA}^2 can cancel.
- The suppression of the double ratio can be controlled by Λ alone clearly.
- The relative factorization breaking effect is seen at the LHC but it is ambiguous at RHIC.

= 200

イロト イポト イヨト イヨト

- Onium production in p+A collisions provides unique opportunity to study gluon saturation phenomena inside high energy hadron/nucleus.
- We need careful calculations since there are soft color exchanges between partonic comover spectator and $c\bar{c}$.
- The CGC+ICEM can provide a systematic description of J/ψ and $\psi(2S)$ production in p+p collisions.
- Recent data of R_{pA} for Onia production at the LHC suggest that factorization breaking effect associated with nuclear enhanced soft color exchanges is significant for $\psi(2S)$ but not so much striking for J/ψ .

Thank you!
