

# Heavy Ion Physics

Yaxian Mao (毛亚显)

Central China Normal University (华中师范大学)

The International summer School on TeV Experimental  
Physics (iSTEP2018)

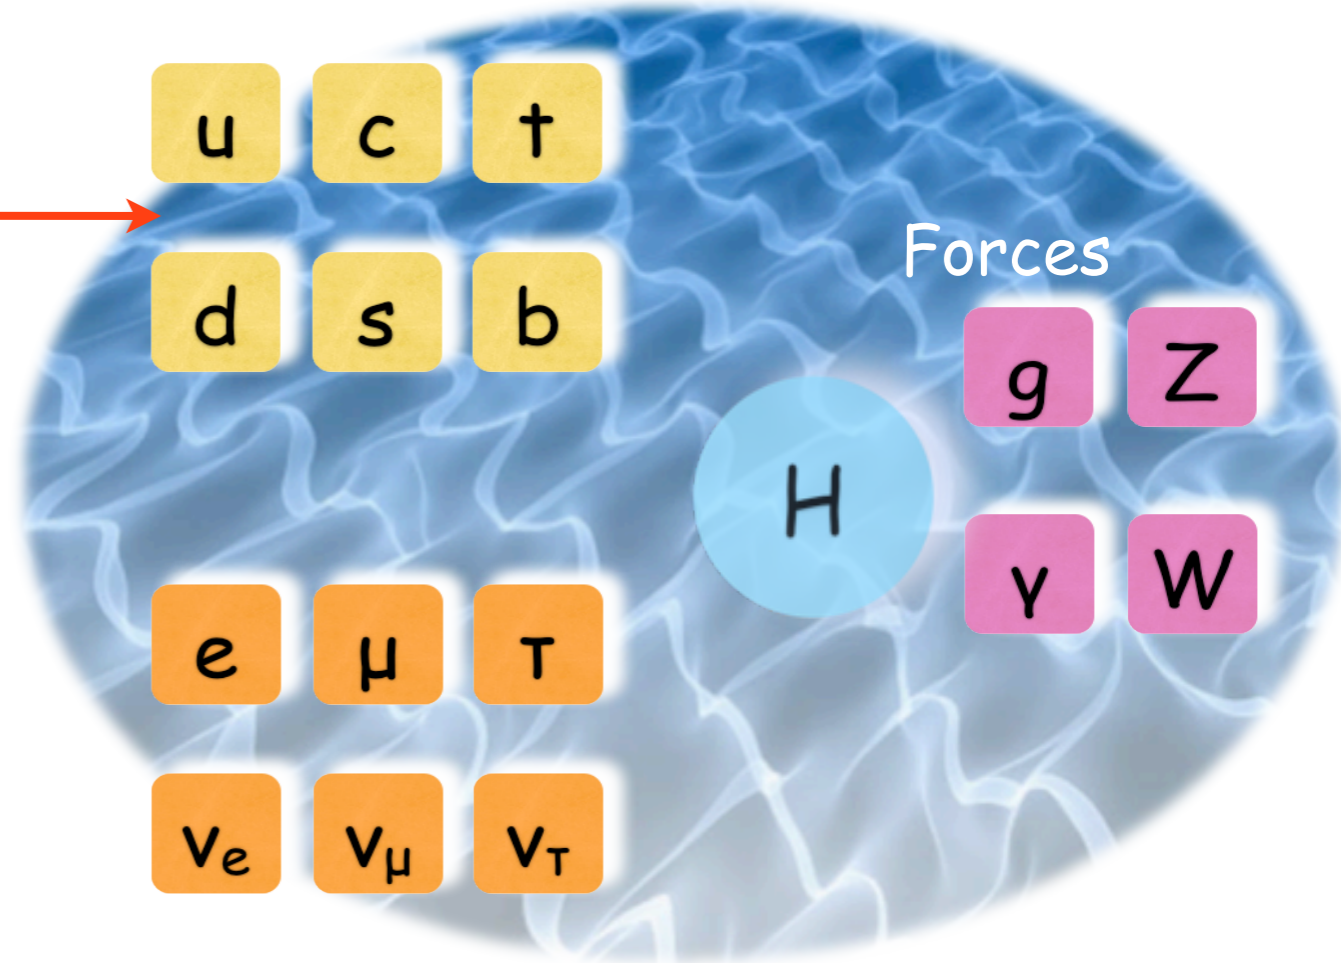

# What is Heavy-Ion Physics

- A way to study **QCD**
  - ... without confinement
  - ... with quarks at their bare masses
- A way to study matter
  - ... at energy densities like  $10 \mu\text{s}$  after the Big Bang
  - ... at temperatures  $10^5$  times larger than in the sun core

# Particles : building blocks of matter!

**You!**  
but also the air you breath, the water you drink, the Sun, galaxies...  
all visible objects in the Universe

# The standard model and QCD

## FERMIONS

matter constituents  
spin = 1/2, 3/2, 5/2, ...

| Leptons spin = 1/2        |                         |                 |
|---------------------------|-------------------------|-----------------|
| Flavor                    | Mass GeV/c <sup>2</sup> | Electric charge |
| $\nu_e$ electron neutrino | $<1 \times 10^{-8}$     | 0               |
| e electron                | 0.000511                | -1              |
| $\nu_\mu$ muon neutrino   | $<0.0002$               | 0               |
| $\mu$ muon                | 0.106                   | -1              |
| $\nu_\tau$ tau neutrino   | $<0.02$                 | 0               |
| $\tau$ tau                | 1.7771                  | -1              |

| Quarks spin = 1/2 |                                 |                 |
|-------------------|---------------------------------|-----------------|
| Flavor            | Approx. Mass GeV/c <sup>2</sup> | Electric charge |
| u up              | 0.003                           | 2/3             |
| d down            | 0.006                           | -1/3            |

## BOSONS

force carriers  
spin = 0, 1, 2, ...

| Unified Electroweak spin = 1 |                         |                 |
|------------------------------|-------------------------|-----------------|
| Name                         | Mass GeV/c <sup>2</sup> | Electric charge |
| $\gamma$ photon              | 0                       | 0               |
| $W^-$                        | 80.4                    | -1              |
| $W^+$                        | 80.4                    | +1              |
| $Z^0$                        | 91.187                  | 0               |

| Strong (color) spin = 1 |                         |                 |
|-------------------------|-------------------------|-----------------|
| Name                    | Mass GeV/c <sup>2</sup> | Electric charge |
| g gluon                 | 0                       | 0               |

- Strong interactions
  - Binds quarks into hadrons
  - Binds nucleons into nuclei
- Described by QCD
  - Interaction between quarks and gluons carrying color charge
  - Mediated by gluons, the strong force carries

Hadrons = particles composed of quarks bound by gluons  
**baryons**: protons, neutrons,  $\Lambda$ , etc : **3 quarks**  
**mesons**: pions, kaons,  $J/\psi$ , etc : **1 quark + 1 antiquark**

# Strong-Interaction Physics

- QCD is a very successful theory ...

e.g. pQCD vs. production of high energy jets

ATLAS, Phys.Rev. D86 (2012) 014022

- But, with outstanding puzzles...

## Hadron Masses

Proton consists of 2 u and 1 d quark  
 $m_p = 938 \text{ MeV} \neq \sim 10 \text{ MeV} = m_{uud}$

Where is the extra mass generated?

## Confinement

Impossible to find an isolated quark or gluon

Why?

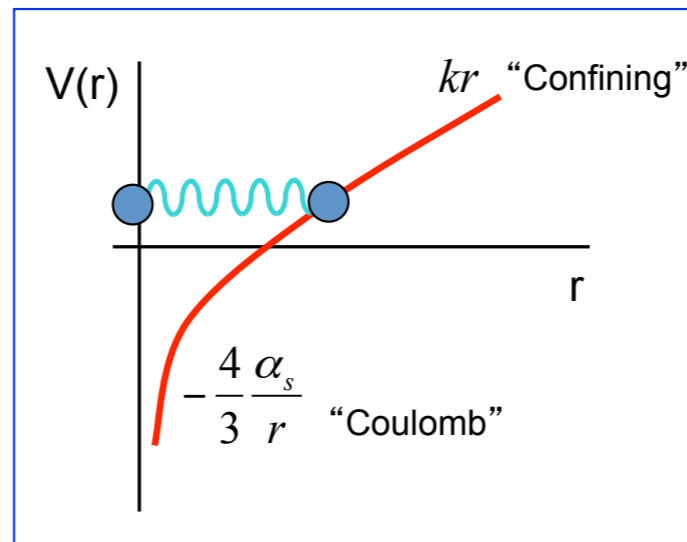

in a regime where perturbative methods are not applicable ... unfortunately

# Confinement

- The increase of the interaction strength (for a  $q\bar{q}$  pair) can be approximated by Cornell potential

$$V(r) = -\frac{4}{3} \frac{\alpha_s}{r} + Kr$$

$Kr$  parametrizes the effects of confinement

- When  $r$  increases, the color field can be seen as a tube
- At large  $r$ , energy in string increases
- New  $q\bar{q}$  pair is created once energy is above production threshold

No free quark can be obtained → confinement

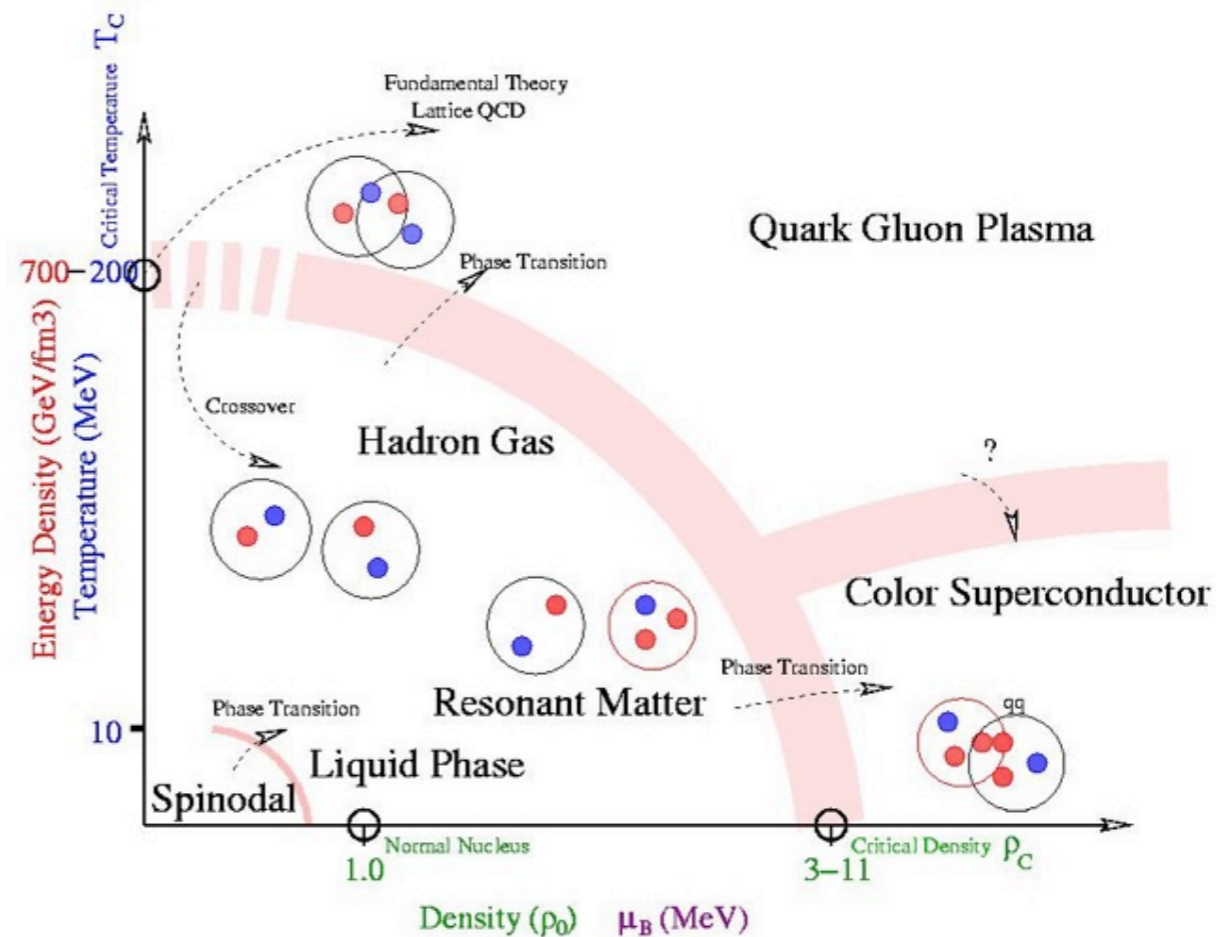

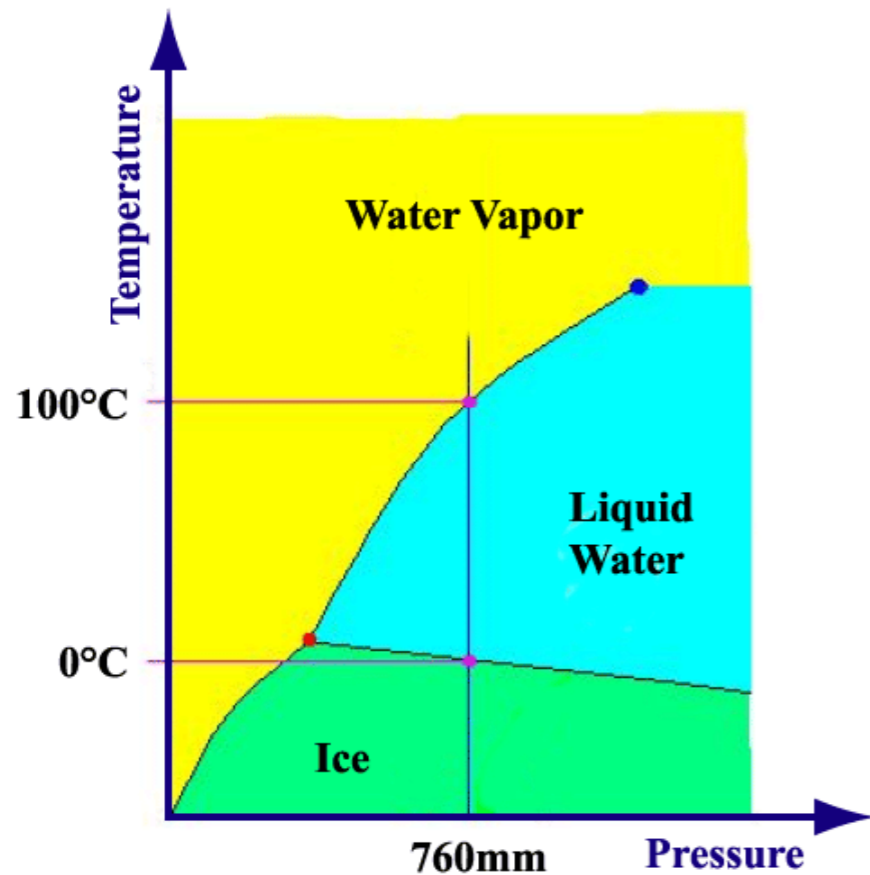

(Illustration from Fritzsche)

# How can one recreate primordial matter of free quarks and gluons ?

# Phase transitions in nature

**QCD** (the strong interaction sector of the Standard Model of particles and forces) predicts:  
“at sufficient high energy density (**provided by HIC**) nuclear matter undergoes a transition from ordinary matter to a new state of matter called the Quark Gluon Plasma (**QGP**)”

# The MIT Bag Model

- The MIT bag model assumes that quarks are confined within bags of perturbative (empty) vacuum of radius  $R$ , in which they are free to move
- The QCD (true) vacuum creates a confining bag pressure  $B$
- The bag constant is obtained by balancing the vacuum with the kinetic pressure of the quarks
- Massless fermions in spherical cavity

$$E = \frac{2.04N}{R} + \frac{4\pi}{3} R^3 B$$

|  |
|--|
| <p><math>N</math> quarks<br/> <math>R</math> radius<br/> <math>B</math> bag pressure</p> |
|--|

- Equilibrium defines bag radius
- Proton radius ( $\sim 0.8$  fm)  $\rightarrow B^{1/4} \sim 206$  MeV

Bag model of a hadron:

$B =$  "bag constant"  $B \approx 0.2 \text{ GeV}/\text{fm}^3$

Chodos et al., PRD 10 (1974) 2599

If kinetic pressure exceeds bag pressure  $\rightarrow$  deconfinement

# Deconfinement phase transition

- If kinetic pressure exceeds bag pressure  $\rightarrow$  deconfinement

- Relativistic massless quark gas

$$p = \left( g_B + \frac{7}{8} g_F \right) \frac{\pi^2 T^4}{90}$$

$$g_B = 16 \quad g_F = 24$$

8 gluons x 2 spins

2 quarks x 2 spins x 3 colors + antiquarks

- Pressure exceeds bag pressure ( $p > B$ ) at  $T_c \sim 144 \text{ MeV}$ 
  - quark-gluon plasma above  $T_c$

More thorough estimate of the phase transition temperature can be done with lattice QCD  $\rightarrow T_c \sim 156 \text{ MeV}$

# Fundamental Questions

- How do “free” quarks and gluons behave?
- How do quarks and gluons behave when chiral symmetry is restored?
- What generates the constituent masses?
  
- In the early universe a phase with free quarks and gluons and restored chiral symmetry has existed
  - Quark-Gluon Plasma (QGP)
  - Recreate in the laboratory with heavy-ion collisions
  
- How does matter behave at very large densities and temperatures?

# QCD Phase Diagram

early universe

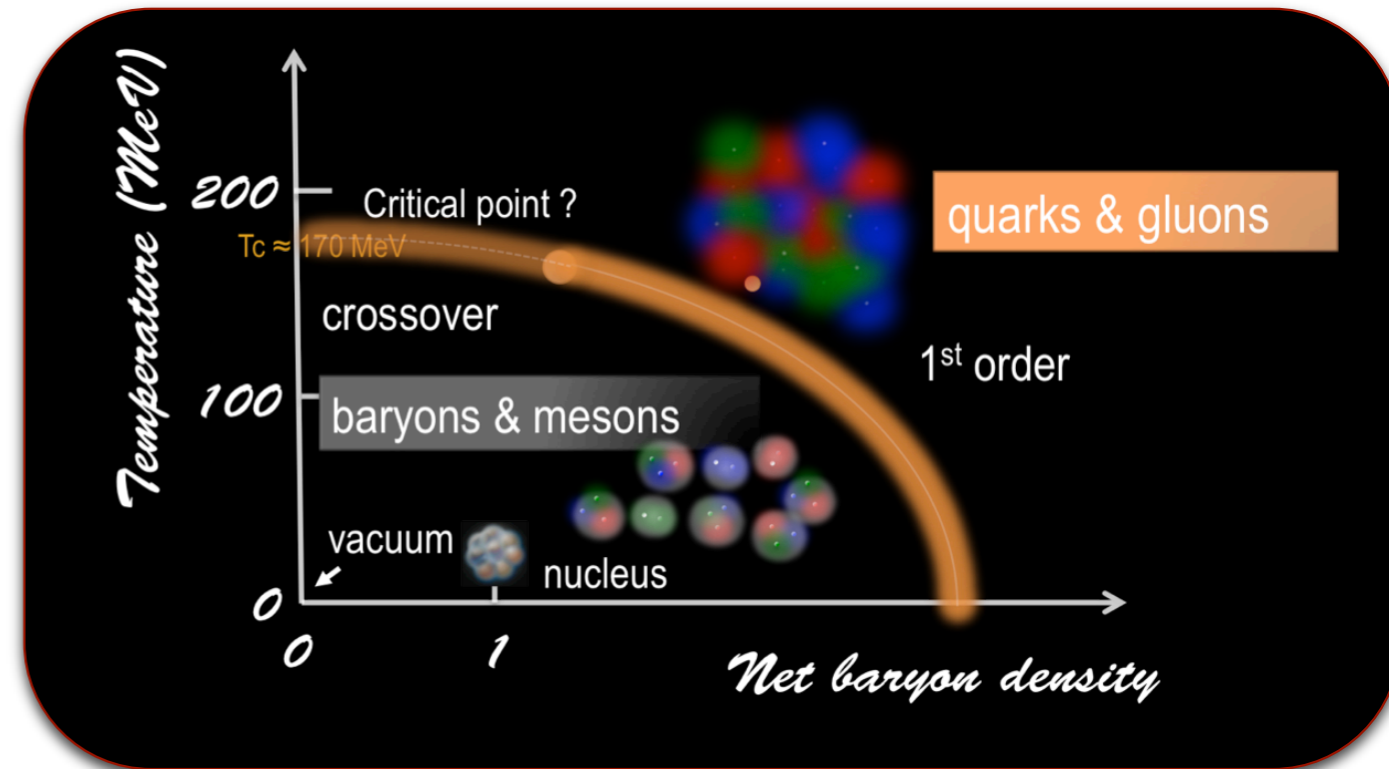

adapted from  
hep-ph/0503184

# The QCD phase transition

- QCD calculations (on the lattice) indicate that the **phase transition** occurs at a critical energy density

We can thus create a system of deconfined quarks and gluons

- ➔ by **heating (T)**
- ➔ by **compression (matter density)**

# QGP factory: Heavy ion collisions

--suggested by T. D. Lee

We collide heavy nuclei at ultra-relativistic energies ( $E \gg mc^2$ ) to produce a droplet of hot ( $T \sim 3-4T_c$ ) matter

Heavy nuclei accelerated at speed of light collide

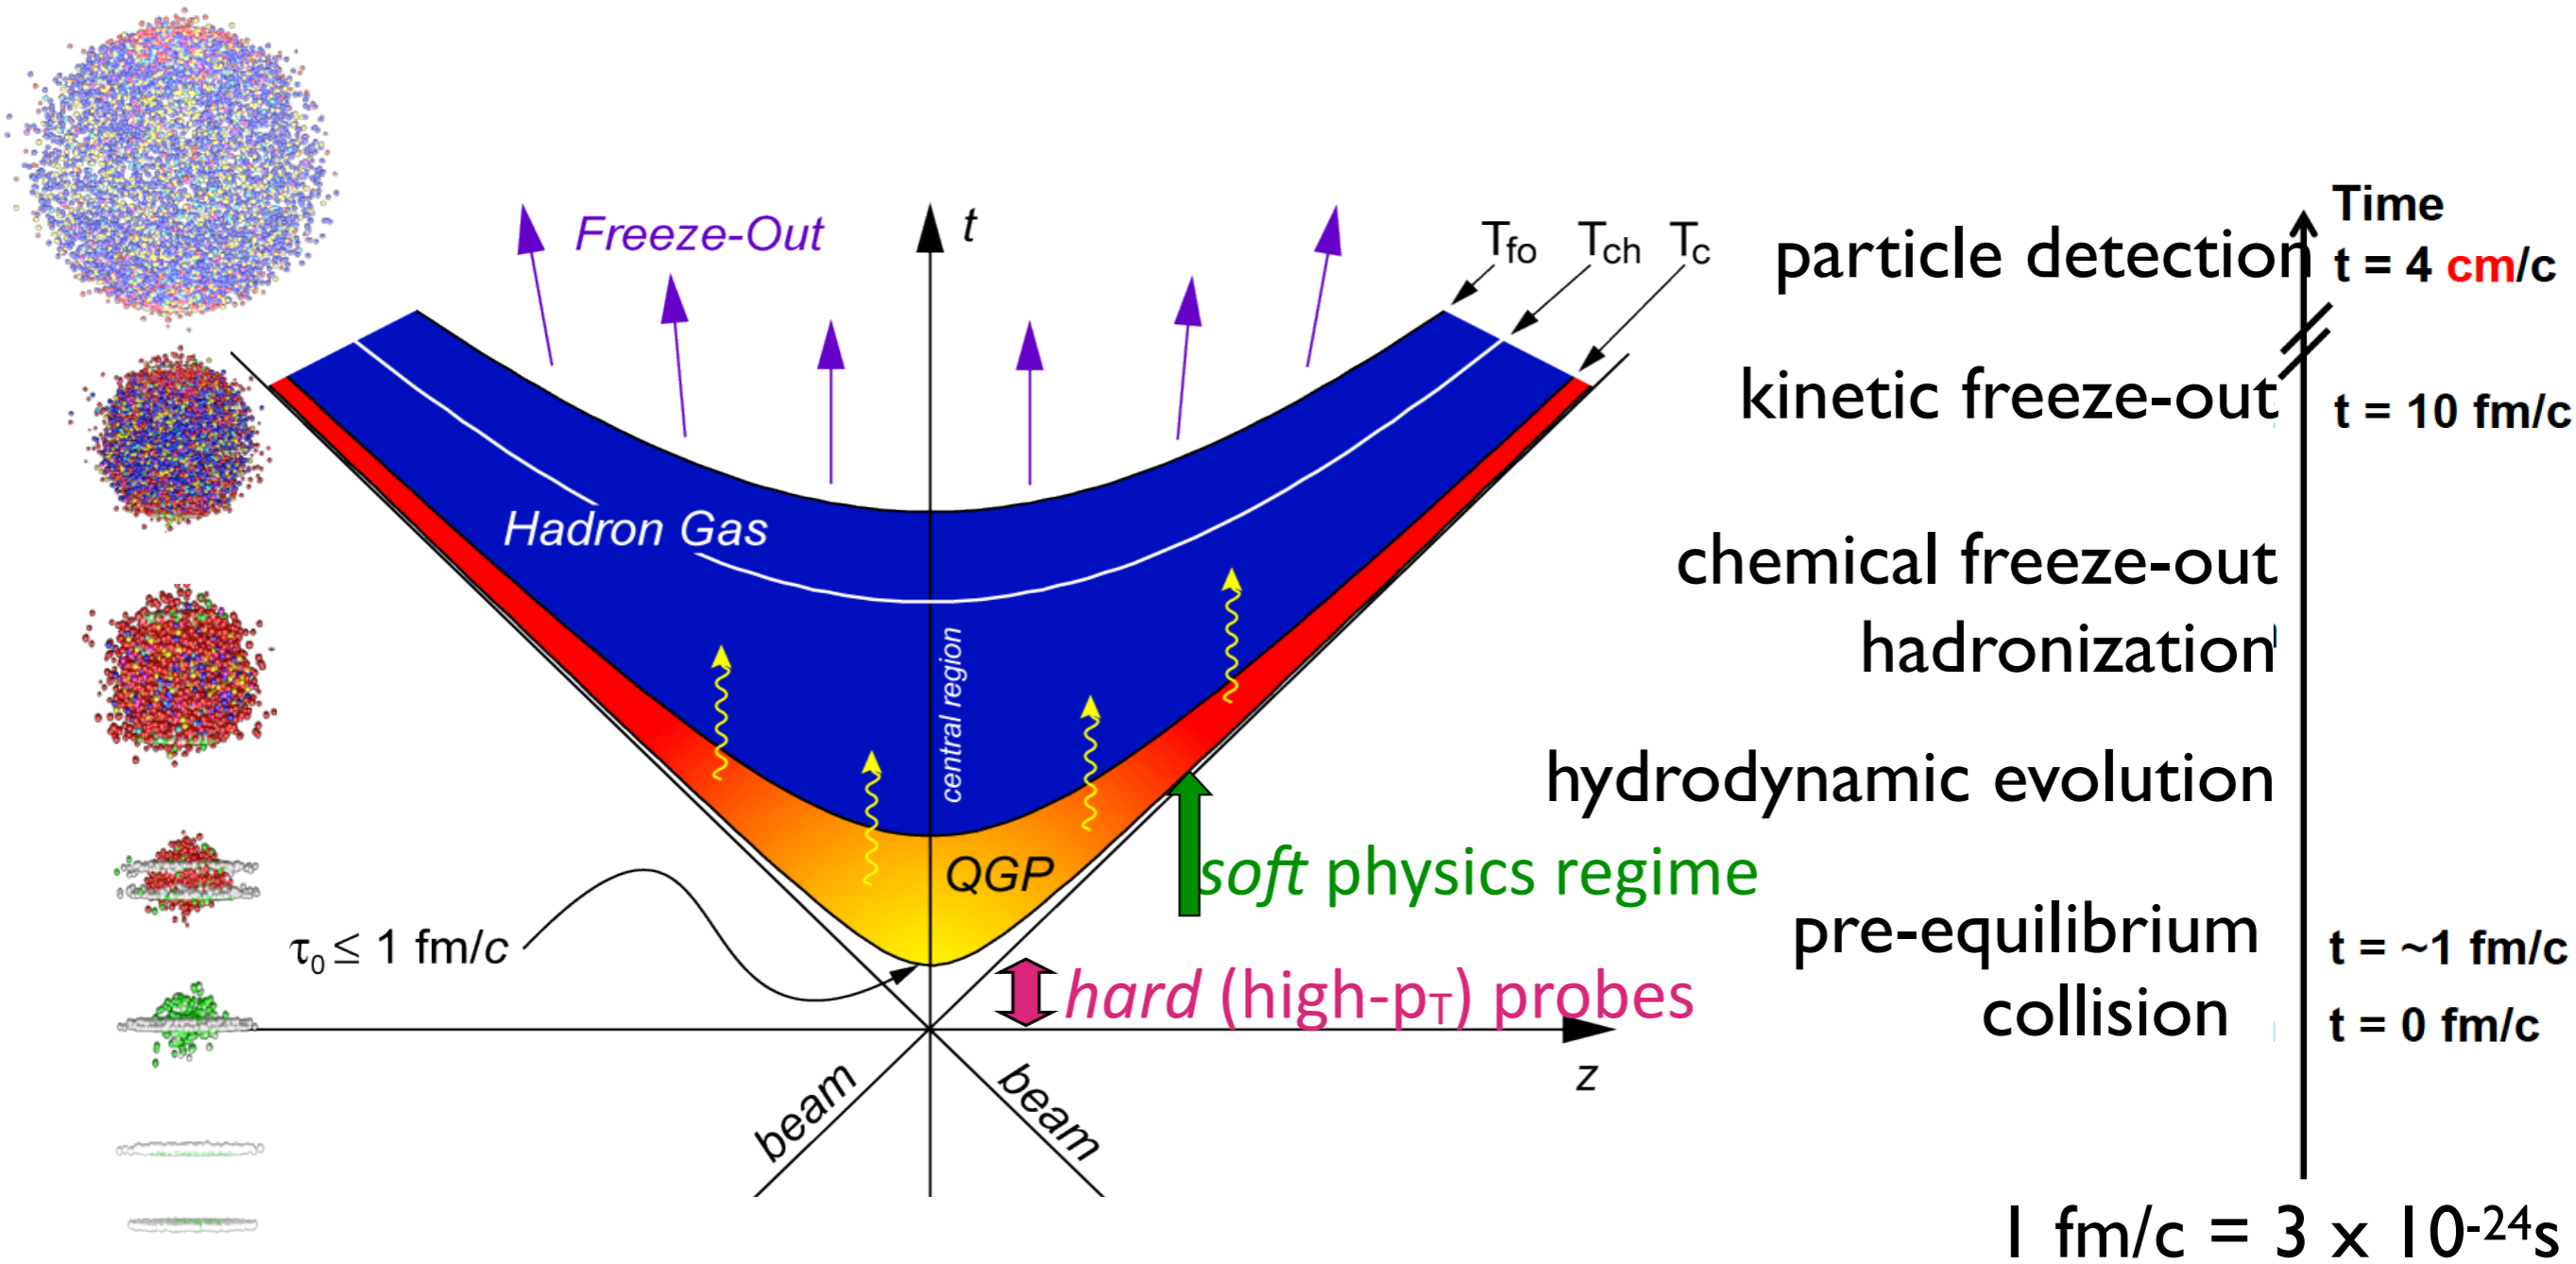

Quarks and gluons are created out of the vacuum ( $E=mc^2$ )

They interact to form a drop of thermalized matter

Matter cools down while expanding

Quarks and gluons condense into observable hadrons

# System evolution in heavy-ion collisions

In reality, strong dynamical evolution of the system ...

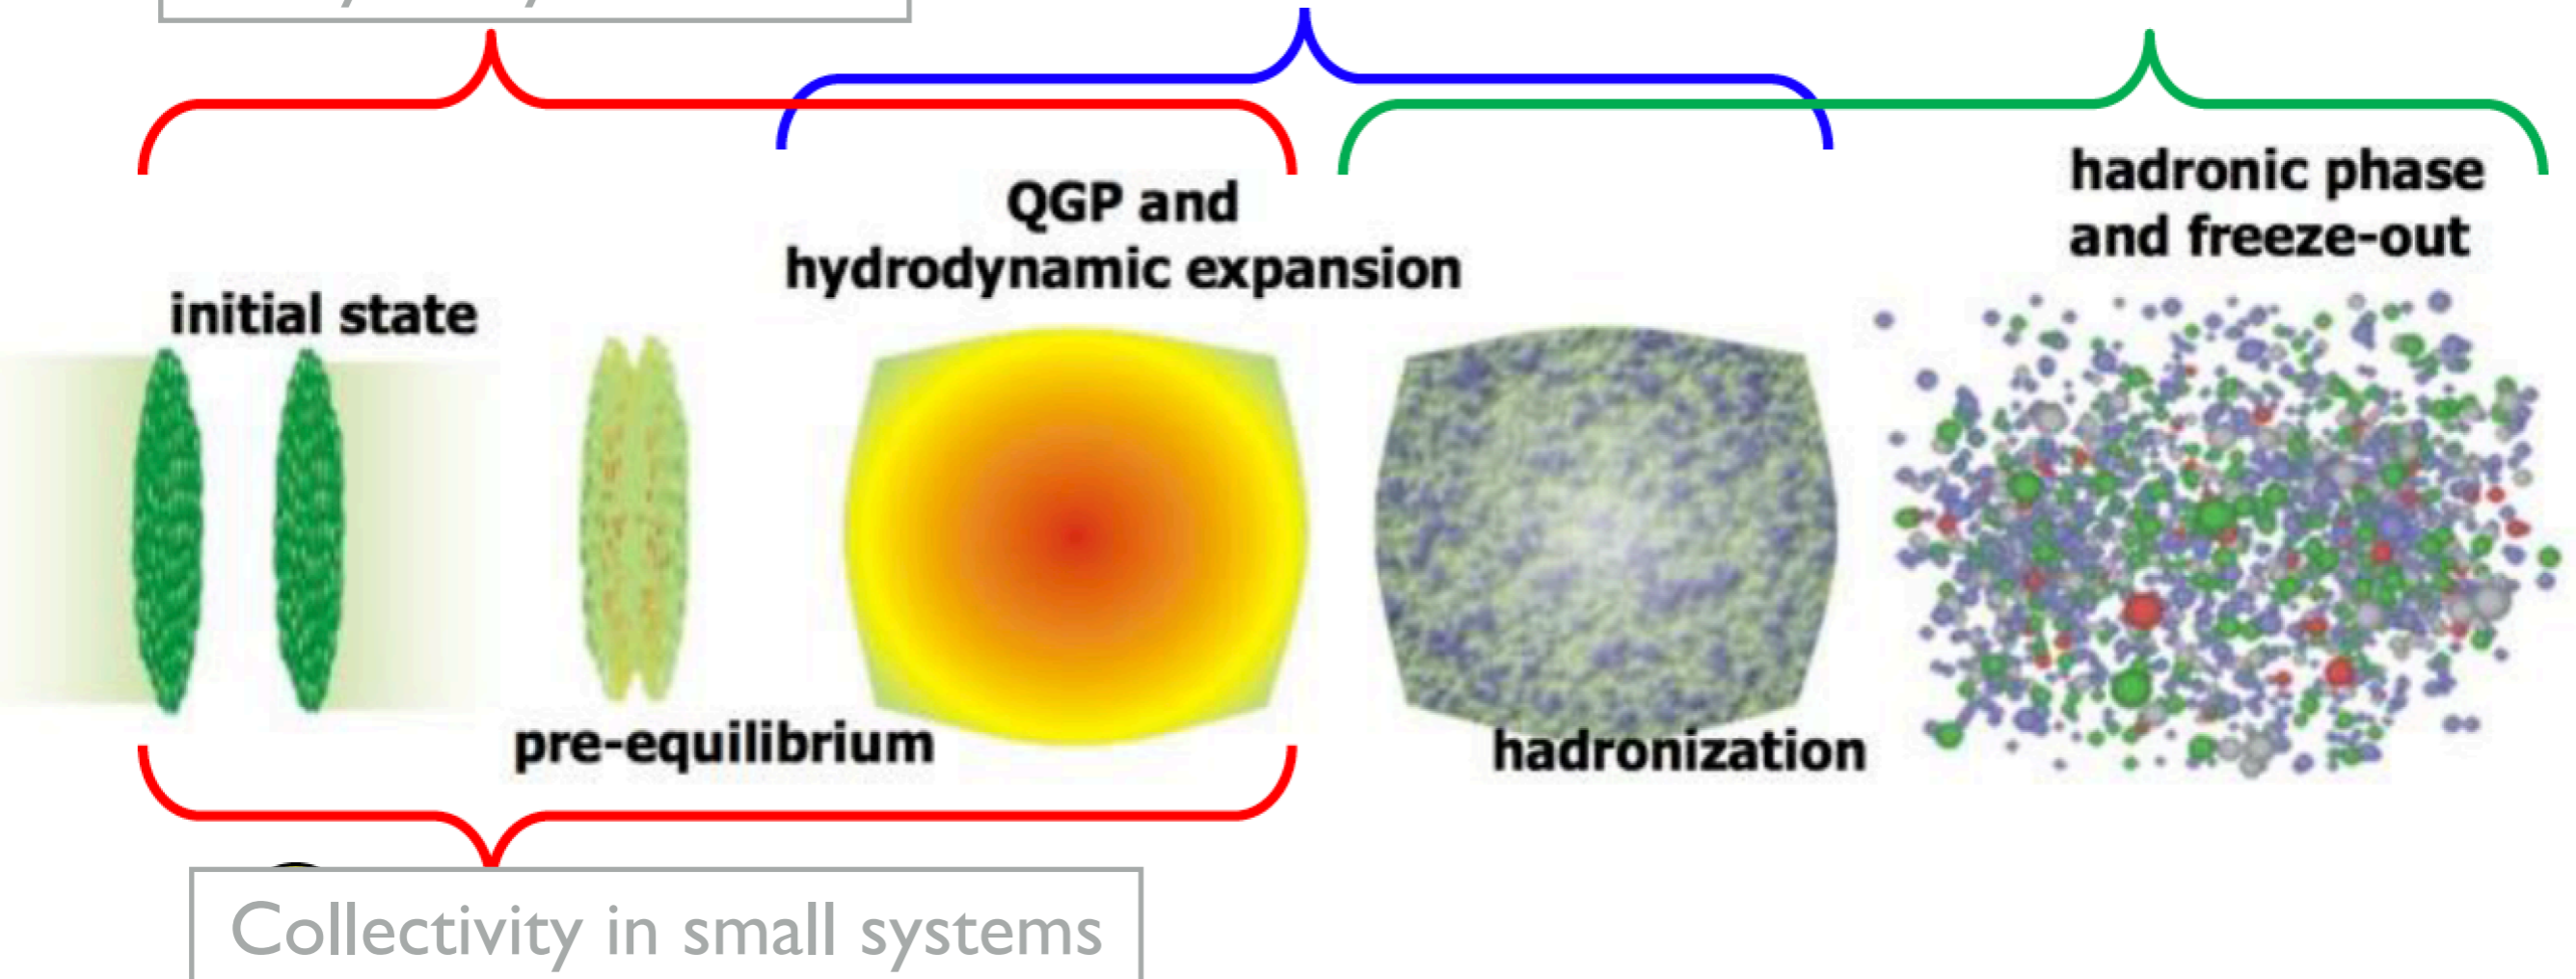

# Outline of the Lecture

- How to use detector to learn about the QGP?
- This lecture will focus on the main topic

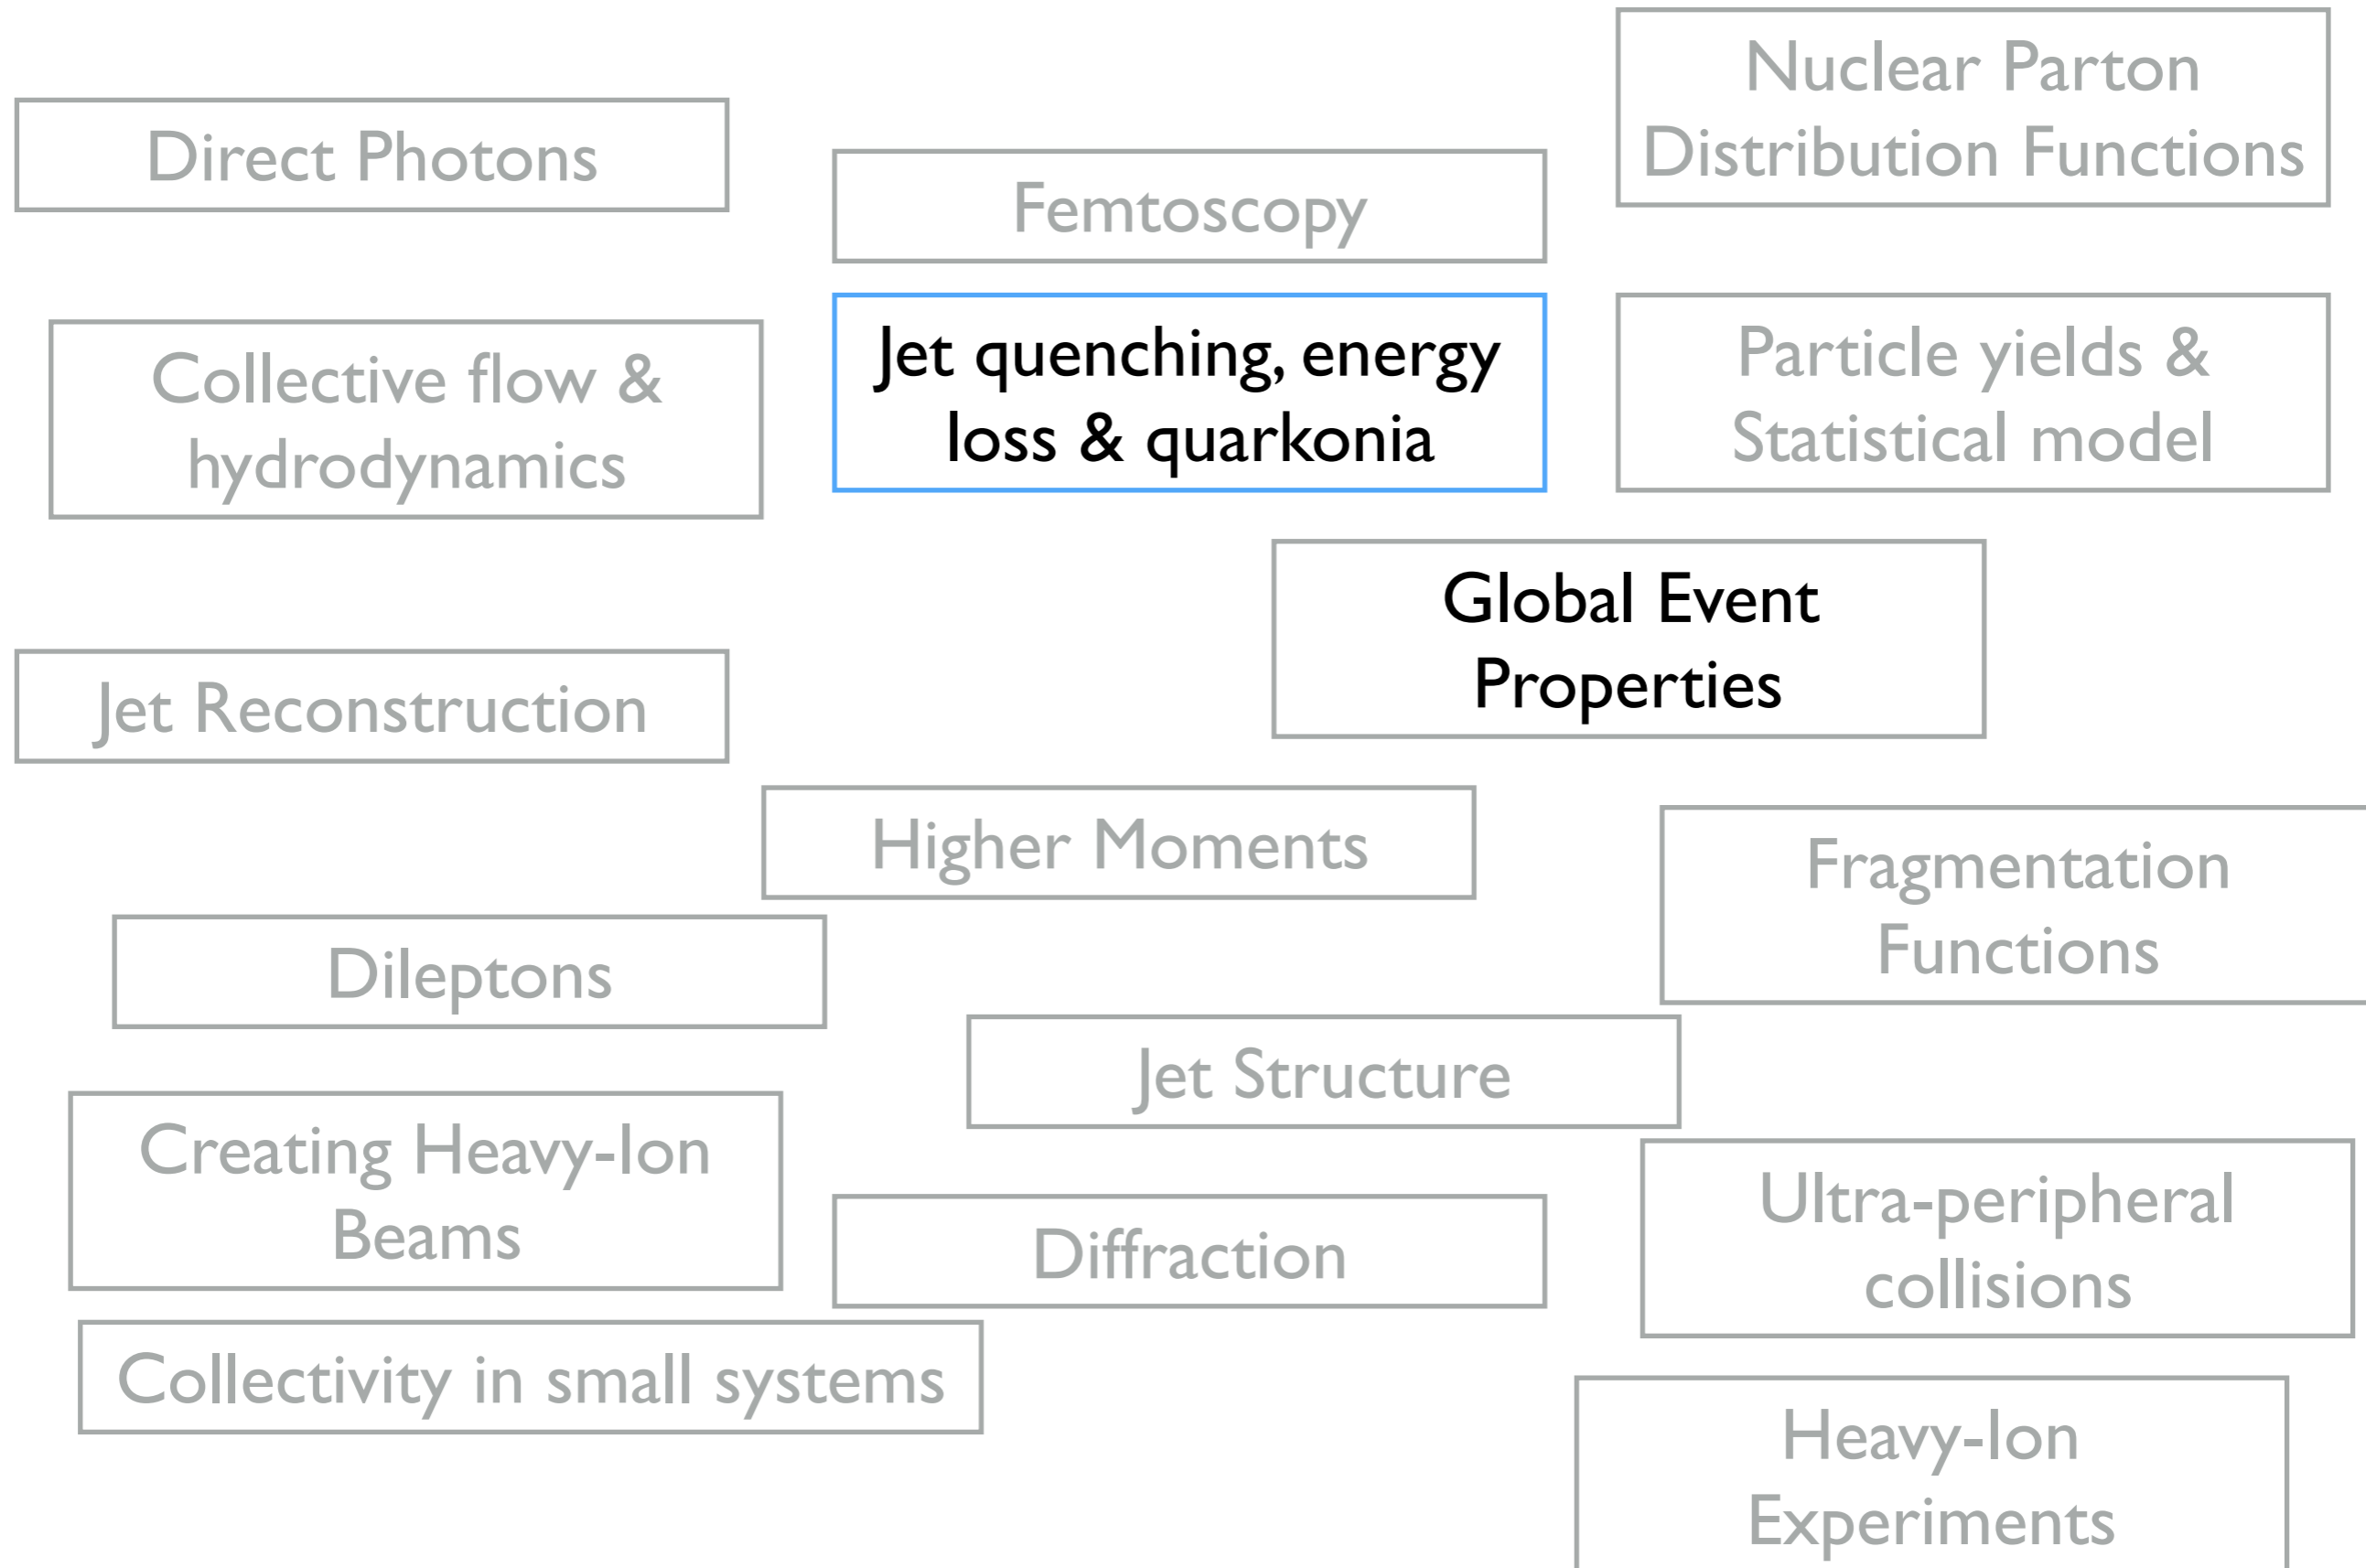

Collective flow & hydrodynamics

Jet quenching, energy loss & quarkonia

Particle yields & Statistical model

# Outline of the Lecture (what I have no time to cover ...)

Volume at freeze-out (fm<sup>3</sup>)

Energy density (GeV/fm<sup>3</sup>)

Life time (fm/c)

Heavy-ion collisions:

$\sqrt{s}$  given per nucleon pair ( $\sqrt{s_{NN}}$ )

$\sqrt{s_{NN}} = 5 \text{ TeV} \rightarrow \sqrt{s_{Pb-Pb}} = 1040 \text{ TeV}$

~3m

NA57 (SPS)

~8m

PHENIX (RHIC)

~16m

ALICE (LHC)

# Two main laboratories for heavy-ion collisions

**AGS** : 1986 – 2000

- Si and Au beams ;  $\sqrt{s} \sim 5$  GeV
- only hadronic variables

**RHIC** : 2000 – ?

- He<sup>3</sup>, Cu, Au beams ; up to  $\sqrt{s} = 200$  GeV
- 4 experiments (only two remain)

**SPS** : 1986 – 2003 + 2009 — ?

- O, S, In, Pb beams ;  $\sqrt{s} \sim 20$  GeV
- Various experiments in North Area

**LHC** : 2009 – ?

- Pb beams ; up to  $\sqrt{s} = 5500$  GeV
- ALICE, CMS, ATLAS and LHCb

# LHC: the Large Hadron Collider

- ALICE dedicated HI experiment
- Low- $p_T$  tracking, PID, mid-rapidity
- Forward-muon spectrometer
- ATLAS/CMS large HEP experiments
- Large acceptance, full calorimetry
- LHCb (pPb in 2013, PbPb since 2015)
- Forward tracking, PID, calorimetry

# Heavy-Ion Environment

- Measurements in an environment with  $dN_{ch}/d\eta$  up to 1600  
( $\sqrt{s_{NN}} = 2.76$  TeV)
  - = 400 pp MB collisions
  - = 1 event with 399 pile-up events
  - (ATLAS/CMS reconstruct up to 100)

for comparison  
pp:  $dN_{ch}/d\eta \sim 4$

- In one collision, there are in the tracker acceptances
  - ▬ 3200 tracks in ALICE | 8000 tracks in CMS/ATLAS

# How to probe QGPs?

# Probing QGP

We study the QCD matter produced in HI collisions by seeing how it affects **well understood probes** as a function of the **temperature of the system** (centrality of the collisions)

# Probes traverse the QGP

Sketch: d'Enterria: arXiv:1207.4362

# External control parameters

# Collision Centrality

Controls the volume, shape and energy density of the system

➔ Multiplicity and energy of produced particles are correlated with geometry of collisions

$$N_{\text{part}} = n_A + n_B$$

$$N_{\text{coll}} = n_A \otimes n_B$$

Soft processes: long timescale, large  $\sigma$ ,  $\sigma_{\text{tot}} \propto N_{\text{part}}$

Hard processes: short timescale, large  $\sigma$ ,  $\sigma_{\text{tot}} \propto N_{\text{coll}}$

How to measure the impact parameter  $b$ ?

# Centrality

- Multiplicity anti-proportional to  $b$ 
  - Glauber MC + particle production model calculates multiplicity
- Multiplicity correlated in different phase space (e.g. forward and mid-rapidity) regions in HI collisions

Low multiplicity

High multiplicity

Striking relation between  $b$  and multiplicity

# Glauber Monte Carlo

- Nucleons travel on straight lines
- Collisions do not alter their trajectory (energy of nucleons large enough)
- No quantum-mechanical interference
- Interaction probability for two nucleons is nucleon-nucleon cross-section

Roy Glauber

“Blue” nucleon has suffered 5 NN collisions

Need to repeat for all other nucleons in A

Strongly dependent on *impact parameter b*

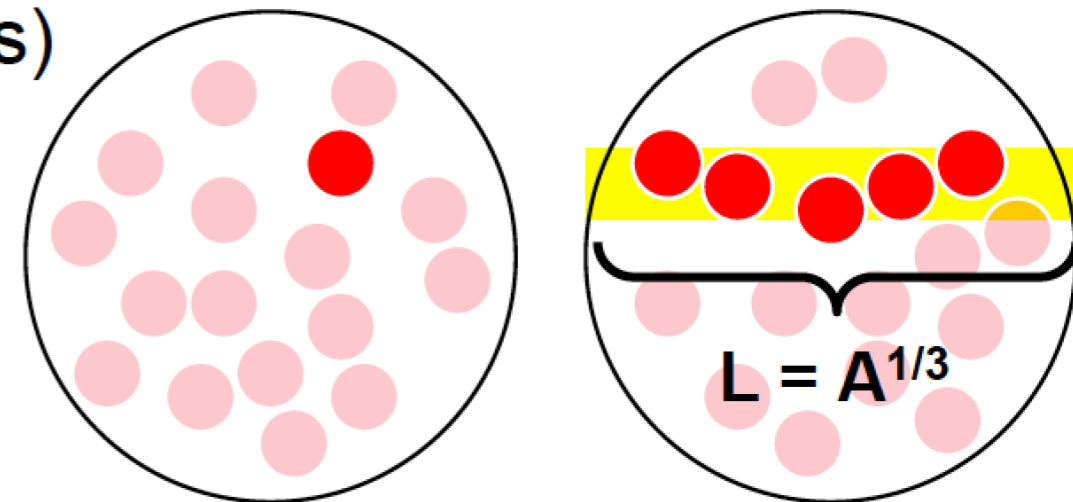

More details in nucl-ex/0701025

# Glauber MC Output

- Number of spectators
  - Nucleons which did not collide
- Participant/wounded nucleons
  - Collided at least once
  - Called  $N_{\text{part}}$
  - Scale with  $2A$  ( $A$  = number of nucleons)
- Number of binary collisions
  - Called  $N_{\text{coll}}$
  - Scales with  $A^{4/3}$
- Rule of thumb
  - Soft (low  $p_T$ ) observables scale with  $N_{\text{part}}$
  - Hard (high  $p_T$ ) observables scale with  $N_{\text{coll}}$

$$N_{\text{part}} \sim A + A$$

$$N_{\text{coll}} \sim A \cdot L = A^{4/3}$$

# Centrality (3)

- Use multiplicity to split events into classes
- Classes 0-5%, 5-10%, ... 100% (“0%” = most central)
- Glauber MC calculates  $N_{\text{part}}$  and  $N_{\text{coll}}$  per class

## Number of events vs. multiplicity

PRC88 (2013) 044909

# Multiplicity and transverse energy

(Estimate of energy density and related to entropy)

# Energy dependence of $dN/d\eta$ and $dE_T/d\eta$

Up  $dN/d\eta \approx 1600$  charged particles in central PbPb at LHC

# Energy dependence of $dN/d\eta$ and $dE_T/d\eta$

Bjorken estimate:

$$\langle \varepsilon \rangle (\tau) = \frac{1}{\tau \pi R^2} \frac{dE_T}{dy}$$

Bjorken, PRD 27 (1983) 140

Up  $dN/d\eta \approx 1600$  charged particles in central PbPb at LHC

Use these measurements to get an estimate of the energy density

# Estimate of energy dependence from $dN/d\eta$

Bjorken estimate:

$$\langle \varepsilon \rangle (\tau) = \frac{1}{\tau \pi R^2} \frac{dE_T}{dy}$$

Bjorken, PRD 27 (1983) 140

- System undergoes rapid evolution
  - Using 1 fm/c as an upper limit for the time needed to “thermalization”
  - Leads to densities above the transition region (also for AGS)
    - However, only necessary not sufficient condition for QPG

$$\begin{aligned} \varepsilon_{\text{BJ}} &= 1.5 \text{ GeV/fm}^3 \text{ for } \sqrt{s_{\text{NN}}} = 5 \text{ GeV} \\ \varepsilon_{\text{BJ}} &= 2.9 \text{ GeV/fm}^3 \text{ for } \sqrt{s_{\text{NN}}} = 17 \text{ GeV} \\ \varepsilon_{\text{BJ}} &= 5.4 \text{ GeV/fm}^3 \text{ for } \sqrt{s_{\text{NN}}} = 200 \text{ GeV} \\ \varepsilon_{\text{BJ}} &= 15 \text{ GeV/fm}^3 \text{ for } \sqrt{s_{\text{NN}}} = 2.76 \text{ TeV} \end{aligned}$$

# Jet Quenching & Energy Loss

How does a quark-gluon plasma affect particles traversing it?

# Hard Probes

- Ideally: a Rutherford experiment

- But
  - QGP exists in the lab only for  $\sim 10^{-23}s$
  - No free color charges as probes
- Instead
  - Use probes generated in the heavy-ion collision itself  
→ “self-generated” probes

# Self-Generated Probes

- Produced early, before the plasma forms  
 $t \sim \hbar/Q, Q > 2 \text{ GeV}/c \rightarrow t < 0.1 \text{ fm}/c$
- Production rate “known”
  - Ideally calculable perturbative
  - Not produced in the medium
- Interact with dense medium (QGP)
- Large cross-section

... as usual there is no such thing as a free lunch ...

## Per central LHC collision

7 D mesons ( $> 2 \text{ GeV}/c$ )  
0.2 B mesons ( $> 10 \text{ GeV}/c$ )  
 $10^{-3}$  jets above 100 GeV  
 $10^{-6}$  jets above 400 GeV

## LHC Run 1 ( $\sim 150/\text{ub}$ )

$10^8$  D mesons ( $> 2 \text{ GeV}/c$ )  
 $10^7$  B mesons ( $> 10 \text{ GeV}/c$ )  
 $10^5$  jets above 100 GeV  
120 jets above 400 GeV

Rec. efficiency,  
branching ratios  
factors  $\sim 1000$

# Hard scattering and jet production

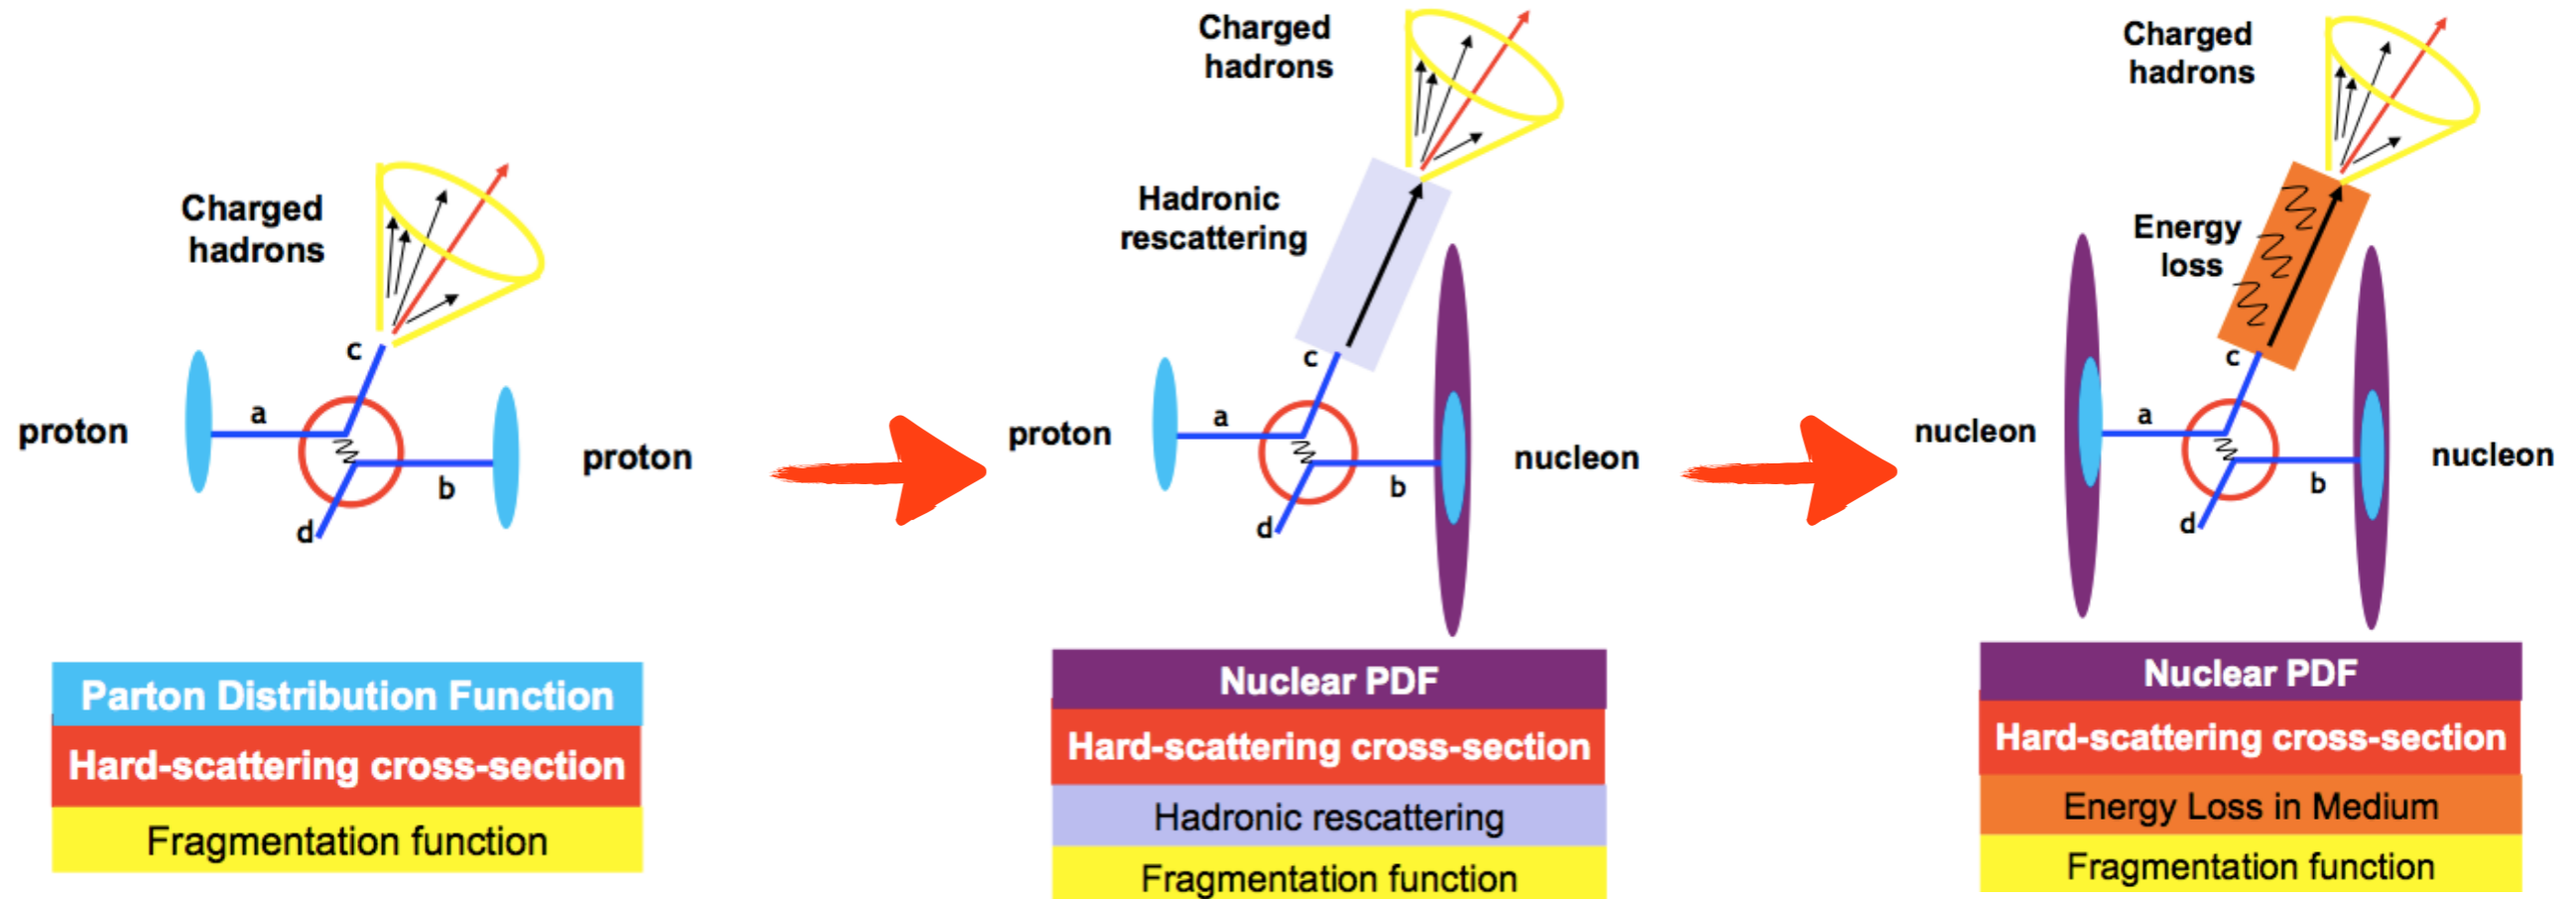

Study the strong force using jet production

- Jets of particles emerge after a high energy parton-parton scattering
- Jet fragmentation function (FF): hadron distribution as a function of  $z$ , defined as the momentum fraction taken by hadron from the jet

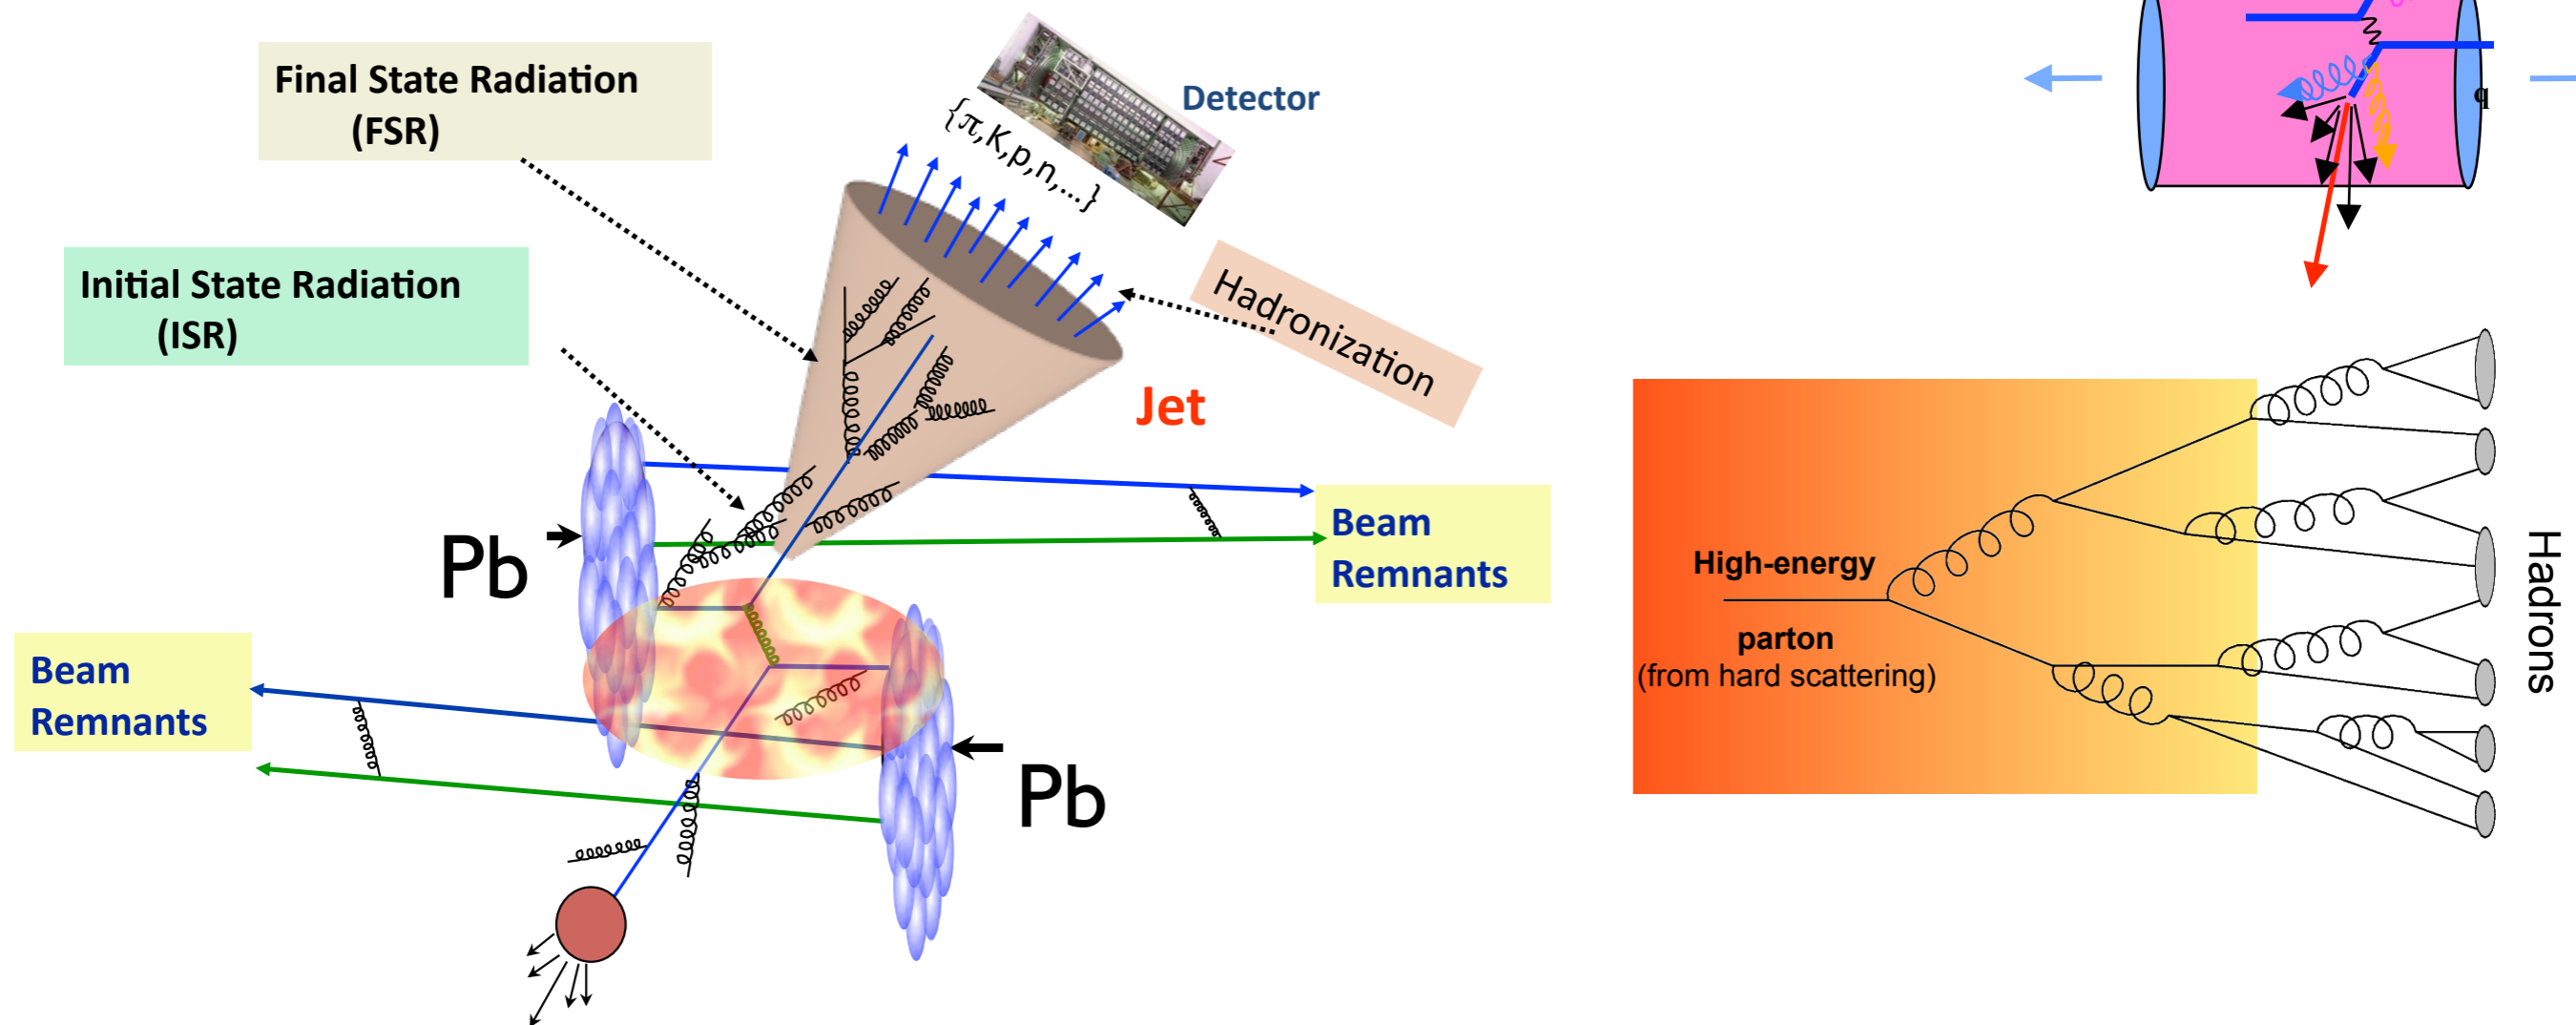

# Nuclear effects in heavy ion collisions

- Disentangle initial and final state effects
- Characterize nuclear PDFs

# Jet-Quenching in QGP

Study the transport properties of the QGP  
a color charge ( $g, q, Q$ ) in a colored medium

- Partons lose energy  $\Delta E$  when traversing the medium (see later slides)
  - $\text{Jet}(E) \rightarrow \text{Jet}(E' = E - \Delta E) + \text{soft particles}(\Delta E)$
- Jet quenching measures 'stopping power' of QGP

# A Back-to-Back Jet

**One jet disappears in the QGP  
→ “Jet quenching”**

ATLAS, PRL 105:252303, 2010  
Drawing: A. Mischke

# Dijet Asymmetry

- How often do jets lose lot of energy?
- Quantify by dijet asymmetry
- 2 highest energy jets with  $\Delta\phi > 2\pi/3$

$$A_J = \frac{|p_{T1} - p_{T2}|}{p_{T1} + p_{T2}}$$

$\xleftarrow{\quad} p_{T1} = p_{T2} \rightarrow A_J = 0$   
 $\xleftarrow{\quad} \frac{1}{3} p_{T1} = p_{T2} \rightarrow A_J = 0.5$

- Peripheral collisions: Pb-Pb ~ Pythia
- Central collisions: Significant difference

Jets lose up to two thirds of their energy!

→ Something significant happening in heavy-ion collisions

# Nuclear-Modification Factor

- Hard processes occur in nucleon-nucleon (NN) collisions
- Heavy-ion collision : many NN collisions
  - Hard process is independent of number of NN collisions
- Without QGP, HI collision is superposition of NN collisions with incoherent fragmentation

$$dN_{AA} / dp_T = \langle N_{coll} \rangle dN_{pp} / dp_T \leftarrow \text{any object, e.g. charged particles, jets, } J/\psi, D, \dots$$

- Let's turn this into an observable

$$R_{AA} = \frac{dN_{AA} / dp_T}{\langle N_{coll} \rangle dN_{pp} / dp_T}$$

$R_{AA} = 1 \rightarrow$  no modification

$R_{AA} \neq 1 \rightarrow$  medium effects

# Nuclear-Modification Factor (2)

- How do we measure this quantity?

For example:

$p_T$  distributions in AA collisions

- select events
- select and count tracks
- correct for detector effects
- estimate systematic uncertainties

$$R_{AA} = \frac{dN_{AA} / dp_T}{\langle N_{coll} \rangle dN_{pp} / dp_T}$$

$p_T$  distributions in pp collisions

Number of binary collisions  $N_{coll}$

- Glauber modeling ([slide](#))
- Centrality ([slide](#))

# Jet $p_T$ distribution in pp and AA collisions

$$R_{AA} = \frac{1}{\langle T_{AA} \rangle} \frac{d^2 N_{AA} / dp_T d\eta}{d^2 \sigma_{pp} / dp_T d\eta}$$

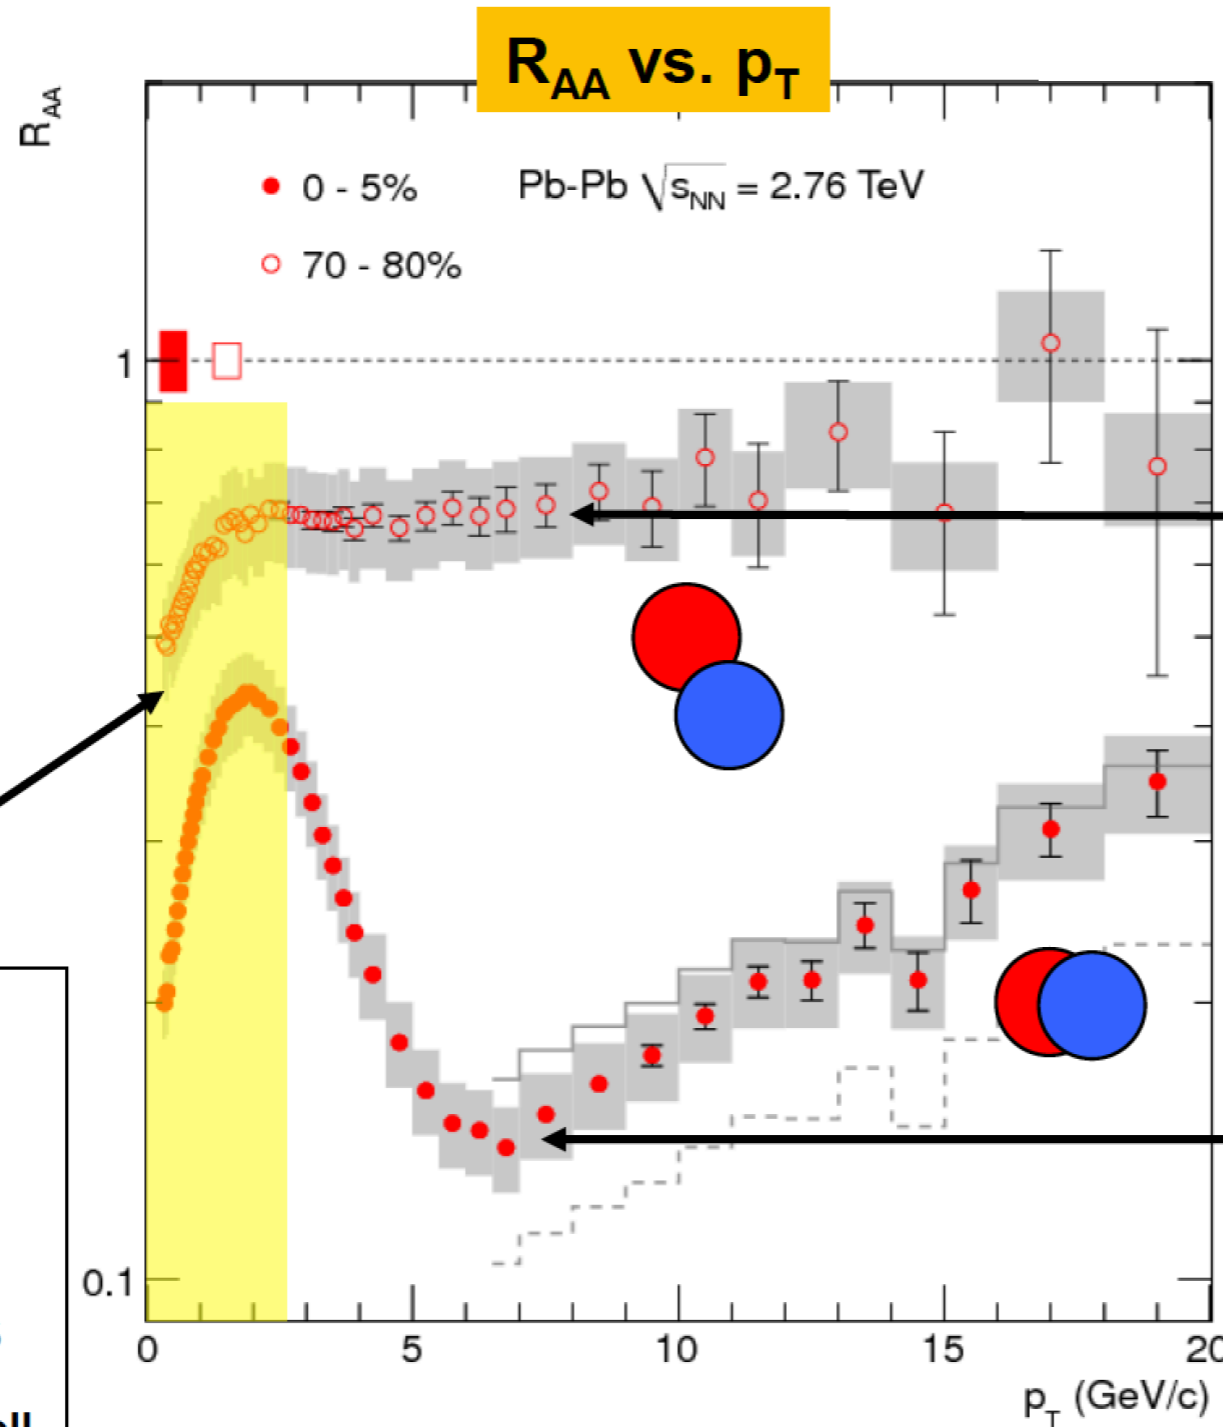

pp@5.02 TeV

Pb-Pb@5.02 TeV

# $R_{AA}$

$$R_{AA} = \frac{dN_{AA} / dp_T}{\langle N_{coll} \rangle dN_{pp} / dp_T}$$

$R_{AA} = 1$   
 $\rightarrow$  no modification

70-80% (peripheral)  
 $\rightarrow R_{AA} \sim 0.7$

0-5% (central)  
 $\rightarrow R_{AA}$  drops to 0.14

Drop at low  $p_T$

Soft particle production does not scale with  $N_{coll}$

ALICE, PLB696 (2011) 30

# $R_{AA}$ at high $p_T$

ATLAS, JHEP09(2015)050

# $R_{AA}$ for Color-Neutral Probes

**No suppression for color-neutral probes**

**→ No interaction with QGP**

**→ Experimental check on  $N_{coll}$  calculation (and nuclear PDFs)**

# Recap

- Peripheral collisions
  - $R_{AA} \sim 0.8 - 0.9$  for colored probes
- Central collisions
  - $R_{AA} \sim 0.14$  at  $p_T \sim 6-7$  GeV/c
  - $R_{AA} \sim 0.6$  at high  $p_T$
- $R_{AA} \sim 1$  for color-neutral probes
- Interpretation
  - $R_{AA} \sim 0.14 \sim 1/7 \rightarrow$  naïve conclusion :  
only 1 out of 7 particles escape the QGP?

**We are looking at a ratio and the particle spectrum is shifted by energy loss**

Strong suppression for high  $p_T$  colored probes in central collisions!

$\rightarrow$  Jet quenching ...

# Energy Loss

- Particle production in central collisions is strongly suppressed

How does the medium achieve this suppression?

# Energy Loss in the QGP

- QGP: high density of quarks and gluons / color sources
- Traversing quark / gluon feels color fields
- Collisional energy loss
  - Elastic scatterings
  - Dominates at low momentum
- Radiative energy loss
  - Inelastic scatterings
  - Dominates at high momentum
  - Gluon bremsstrahlung

$$\Delta E = \Delta E_{\text{coll}} + \Delta E_{\text{rad}}$$

Lect. Notes Phys. 785,285 (2010)

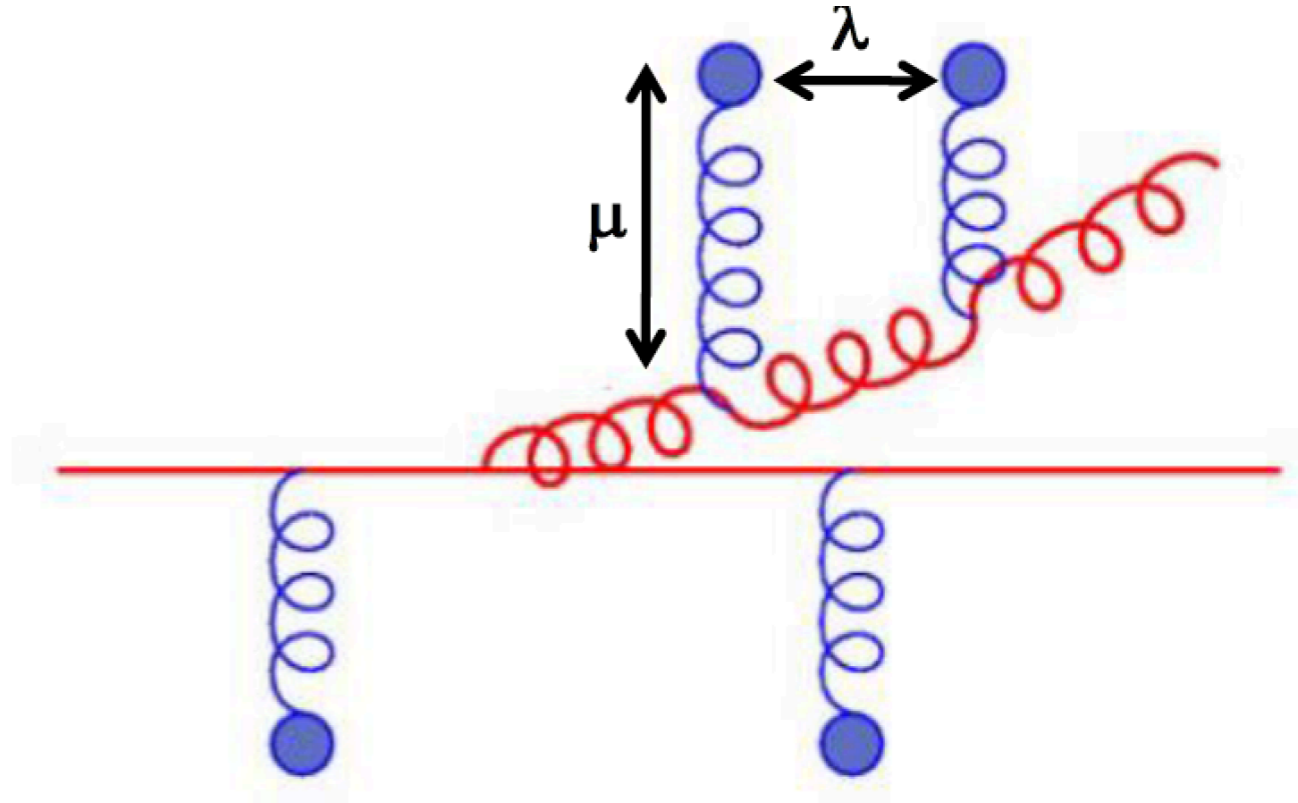

# Radiative Energy Loss

- BDPMS formalism
  - Baier, Dokshitzer, Mueller, Peigné, Schiff
  - Infinite energy limit
  - Static medium

$$\Delta E \sim \alpha_S C_R \hat{q} L^2$$

- Energy loss depends on

- Path length through medium **squared**
- Casimir factor
  - $C_R = 4/3$  (quarks)
  - $C_R = 3$  (gluons)
- Medium parameter “q hat”

**L path length, driven by:**

- gluon-gluon self interactions
- quantum interference

$$\hat{q} = \frac{\mu^2}{\lambda}$$

← average transverse momentum transfer

← mean free path

Baier, Dokshitzer, Mueller, Peigné, Schiff, NPB 483 (1997) 291

# Dead Cone Effect

- Due to kinematical constraints, gluon radiation in vacuum suppressed for angles  $\theta < m/E = 1/\gamma$  by  $\left(1 + \frac{m/E}{\theta}\right)^2$ 
  - Massless parton  $m = 0 \rightarrow$  no suppression

- Similar effect in the medium
  - Significant for charm and beauty
  - Radiative energy loss reduced by 25% (c) and 75% (b) [ $\mu = 1 \text{ GeV}/c^2$ ]
- Implies quark mass dependence

$$R_{AA}^{\pi} < R_{AA}^D < R_{AA}^B$$

PLB519:199-206,2001

Lect. Notes Phys. 785,285 (2010)

# Collisional Energy Loss

- For light quarks and gluons

$$\Delta E_{q,g} \sim \alpha_S C_R \mu^2 \boxed{L} \ln \frac{ET}{\mu^2}$$

- For heavy quarks additional term

$$\alpha_S^2 T^2 C_R \mu^2 \boxed{L} \ln \frac{ET}{M^2}$$

- Energy loss depends on

- Path length through medium **linear**
- Parton type (light or heavy)
- Temperature T
- Mass of heavy quark M
- Medium parameter  $\mu$  (average transverse momentum transfer)

PRD 77, 114017 (2008) 291

# Recap

- We have seen significant suppression of charged hadron spectra
  - Dominated by light quarks / gluons...
  - ... which at low  $p_T$  are also produced within the medium
- Energy loss occurs by radiative and collisional processes
- Theoretical calculations extract medium properties like density, average momentum transfer, mean free path,  $\hat{q}$
- Calculations more accurate for heavy quarks
- Dependence of energy loss on quark mass expected

Let's measure energy loss with heavy quarks!

# Heavy Quarks

- Charm ( $m \sim 1.3 \text{ GeV}/c^2$ )
- Beauty ( $m \sim 4.7 \text{ GeV}/c^2$ )
- Produced in hard scattering
- Essentially not produced in the QGP
- Expectation

$$R_{AA}^{\pi} < R_{AA}^D < R_{AA}^B$$

- LHC:  $\sim 7 D > 2 \text{ GeV}/c$  per central event

# D<sup>0</sup> Reconstruction

- D<sup>0</sup> meson:  $m = 1.87 \text{ GeV}/c^2$  ;  $c\tau = 123 \text{ }\mu\text{m}$ 
  - Rather short lived
  - Many decay modes
  - $D^0 \rightarrow K \pi$  (branching ratio 3.9%)
- Standard method: invariant mass of opposite charge pairs
  - Per central event ( $D^0 \rightarrow K \pi$ ,  $> 2 \text{ GeV}/c$ , incl. efficiencies):  
0.001 compared to  $\sim 700$  K and up to  $\sim 2500$   $\pi$
  - Signal over background far too small to extract a peak
- Reduce combinatorial background (see next slides)
  - Topological cuts
  - Particle identification (PID) of K and  $\pi$

# Topological Cuts

3) Require distance of primary and secondary vertex (impact parameter) [ $\sim 100 \mu\text{m}$  challenging for pixel detectors!]

2) Require that K and  $\pi$  share a secondary vertex

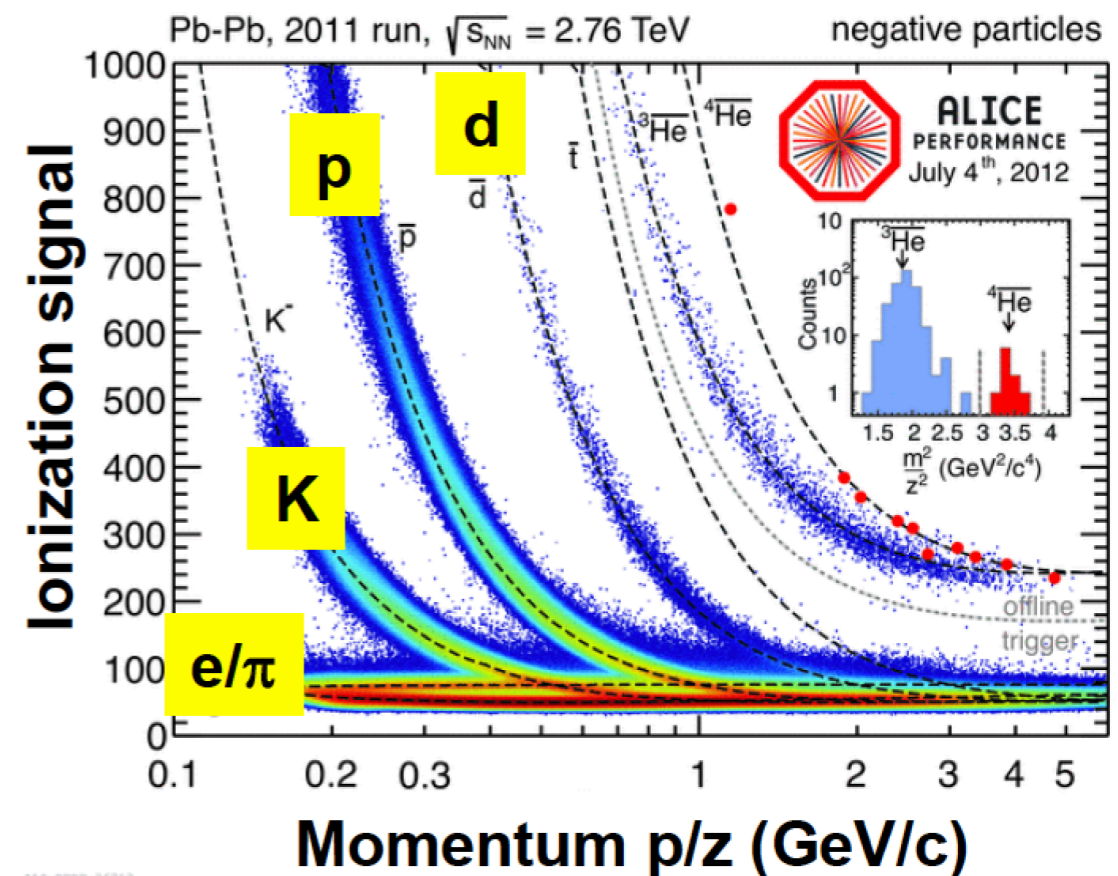

1) Require large impact parameter tracks

Plane transverse to beam

4) Require pointing angle  $\theta$  to be small

# Particle Identification (PID)

- Specific Energy Loss
  - Particles passing through matter lose energy mainly by ionization
  - Average energy loss calculated with Bethe-Bloch formula
  - Identify particle by measuring energy deposition and momentum
- Time Of Flight
  - Particles with the same momentum have slightly different speed due to their different mass
  - Needed flight time precision, e.g. for a particle with  $p = 3 \text{ GeV}/c$ , flying length 3.5 m:  
 $t(\pi) \sim 12 \text{ ns} \mid t(K) - t(\pi) \sim 140 \text{ ps}$
- Methods can be combined

# Invariant Mass with Cuts

- $D^0 \rightarrow K \pi$

PID reduces background, but signal peak stays of same magnitude

# Recap: D Meson Yield

- We would like to learn about the energy loss of charm
- Reconstruct D meson decay to  $K \pi$ 
  - Rare signal
  - Combinatorial background reduced with particle identification and topological cuts
  - Invariant mass distribution
  - Background with like-sign combinations
  - Apply fit to extract yield

PRC 90 (2014) 034904

# D $R_{AA}$

## $R_{AA}$ vs. centrality

strong suppression  $\sim 0.2$

$$R_{AA} = \frac{dN_{AA} / dp_T}{\langle N_{coll} \rangle dN_{pp} / dp_T}$$

## $R_{AA}$ vs. $p_T$

D and  $\pi$   $R_{AA}$  compatible

arXiv:1506.06604

# $\pi R_{AA}$ vs. $D R_{AA}$

- Expectation  $R_{AA}^{\pi} < R_{AA}^D < R_{AA}^B$
- However  $R_{AA}^{\pi} \approx R_{AA}^D$
- Are the energy loss models wrong?
- Not necessarily
  - Effect expected for  $p_T$  close to charm mass ( $\sim 1.3 \text{ GeV}/c^2$ )
  - Uncertainties on  $D R_{AA}$  large for  $p_T < 5 \text{ GeV}/c$
  - Fragmentation ( $\rightarrow$  hadron) different for gluons and quarks

Let's have a look at particles containing a heavier b ...

# B $R_{AA}$

$B^\pm \rightarrow (J/\psi \rightarrow \mu\mu) + X$  identified by displaced secondary vertices (see [backup](#))

**D is stronger suppressed than B !  $\rightarrow$  hint of quark mass dependence**

- $R_{AA}(J/\psi \leftarrow B) > R_{AA}(D) \approx R_{AA}(\pi)$  how to explain such mass dependence?

# Summary

- An extremely dense and strongly coupled medium has been produced at LHC in central PbPb collisions:  $T \gg T_c$
- External probes ( $l/p_T, l/Q \gg t_0$ ) are used to determine the medium fundamental properties (thermodynamic properties, transport properties, degrees of freedom,...)
- The HI program has moved beyond the initial exploration phase and is now producing detailed and precise measurements
  - Need detailed and precise theoretical description of entire collision dynamics
  - Many new results and also many open questions (pA and high multiplicity pp !!)
- Improving understanding on QGP properties using newly coming data at LHC ongoing

**Thank you for your attention!**

# Chiral Symmetry

- QCD Lagrangian symmetric under  $SU(2)_L \times SU(2)_R$
- Light quarks have finite (small) bare masses
  - Explicit chiral symmetry breaking
- Creation of coherent  $q$ - $\bar{q}$  pairs in QCD vacuum (compare to cooper pairs in superconductivity)
  - Has a chiral charge
  - Not symmetric under  $SU(2)_L \times SU(2)_R$
  - Spontaneous symmetry breaking (pseudo-goldstone bosons: pions)
- Quarks acquire  $\sim 350$  MeV additional mass
  - *Constituent mass*
  - Relevant only for  $u, d, s$

|  |                |
|--|----------------|
| $\Sigma p = 0$                                     | $\Sigma L = 0$ |
| $\rightarrow$ <b>chirality <math>\neq 0</math></b> |                |

# Lattice QCD

- More thorough estimate of the phase transition temperature can be done with lattice QCD
- Approach to solve non-perturbative QCD
- Discretize the QCD Lagrangian on a space-time grid
- Limited to chemical potential  $\mu_B = 0$  (some workarounds exist)
- Calculate T dependence of
  - energy density
  - pressure
- Steep rise = change in number of degrees of freedom  
→ phase transition

$\epsilon/T^4, 3p/T^4$  vs. T

non-int. limit

HRG

$3p/T^4$

$\epsilon/T^4$

$3s/4T^3$

T [MeV]

PRD90 094503

156 MeV  $\approx 2 \cdot 10^{12}$  K  
(Sun core:  $1.5 \cdot 10^7$  K)

Transition temperature  $T_c \sim 156$  MeV  
(consistent with bag model estimate)
