# Outline

- ◆ Motivation
- ◆ Data sample
- ◆ Measurement of branching ratio of  $\chi_{cJ} \rightarrow p\bar{p}$ 
  - Event selection
  - Background estimation
  - Fit
- ◆ Systematic uncertainties of branching ratio
- ◆ Measurement of angular distribution of  $\chi_{cJ} \rightarrow p\bar{p}$
- ◆ Systematic uncertainties of angular distribution
- ◆ Summary

# Motivation

- In theory, the process of  $\chi_{c0} \rightarrow p\bar{p}$  obeys *helicity selection rule* [1], *but we observed the larger branching ratio.*
- *The* experimental measurements of the branching ratio are much higher than the predictions by Color Singlet Model (CSM), but it seems to be explained well by Color Octet Mechanism (COM). More accurate experimental measurements will help us in understanding the decay mechanism.
- BESIII has collected 448.1 M  $\psi(2S)$  events . With the largest  $\psi(2S)$  data sample, we can give more precise results.

## ➤ Tracking

$$|V_r| < 1\text{cm}, |V_z| < 10\text{cm}$$

$$|\cos\theta| < 0.93$$

$$\text{NCharge}=2$$

$$\text{Total charge}=0$$

## ➤ Official requirements for photon

$$E_r^{\text{endcup}} \geq 50\text{Mev} (0.86 < |\cos| < 0.92)$$

$$E_r^{\text{barrel}} \geq 25\text{Mev} (|\cos| < 0.80)$$

$$m_{\text{gammaAngleCut}} > 20,$$

$$n_{\text{gamma}} \geq 1$$

$$\text{TOF} (0 \sim 14)$$

## ➤ PID(use dE/dx and TOF)

$$P(p) > 0.001 \text{ and } P(p) > P(k) \text{ and } P(p) > P(\pi) \text{ for } p,$$

$$\text{Change} > 0 \text{ for } p, \text{ change} < 0 \text{ for } \bar{p}$$

# The $\chi_{4c}^2$ of kinematic fit optimization

Finally, a four-constraint (4C) kinematic fits are performed to improve resolution and help to suppress background. The left plot shows the distribution of  $\chi_{4c}^2$ .

The right plot shows the  $\chi_{4c}^2$  distribution of 4-C fit optimized based on the figure-of-merit(FOM) defined as  $S/\sqrt{S+B}$ . The background(B) and signal(S) are obtained from the inclusive MC simulation. So the  $\chi_{4c}^2$  is determined to be less than 60. The point with error bars are data, the red line denotes inclusive mc, the blue line denotes signal mc of  $\chi_{c0}$ , the black dotted line denotes signal mc of  $\chi_{c1}$ , the green line denotes signal mc of  $\chi_{c2}$ ,

# Check the algorithm

| Channel                          | N (fit)       | N(inclusive mc) |
|----------------------------------|---------------|-----------------|
| $\chi_{c0} \rightarrow p\bar{p}$ | $6068 \pm 92$ | 6092            |
| $\chi_{c1} \rightarrow p\bar{p}$ | $2011 \pm 50$ | 2031            |
| $\chi_{c2} \rightarrow p\bar{p}$ | $1732 \pm 49$ | 1796            |

# Background Study

## Main Backgrounds:

1.  $\psi' \rightarrow \gamma p \bar{p}$
2.  $\psi' \rightarrow p \bar{p} \gamma_{\text{FSR}}$
3.  $\psi' \rightarrow \pi^0 p \bar{p}$
4. Continuum background

The left plot shows the distribution of  $M(p\bar{p})$  compared with data and MC in the  $\chi_{cJ} (J = 0, 1, 2)$  mass range from 3.30 GeV to 3.60 GeV.

We use the data taken at the energy point 3.65 GeV to estimate the contribution from continuum background and the right plot shows the invariant mass spectrum after shifting and scaling. The scale factor is:

$$f_{\text{continuum}} = \frac{156.4 \text{ pb}^{-1} + 500 \text{ pb}^{-1}}{44 \text{ pb}^{-1}} * \left( \frac{3.65 \text{ GeV}}{3.686 \text{ GeV}} \right)^2 = 12.1$$

Considering the energy difference, we shift the mass according to the operation,  $m \rightarrow \frac{(3.686 - m_0)}{(3.65 - m_0)}(m - m_0) + m_0$

# Background Study

The black histograms show the backgrounds from inclusive MC, respectively. The blue histogram shows all backgrounds from inclusive MC after the signals are removed. The number of backgrounds from inclusive MC after all event selections is less than the number of signals. All of these backgrounds in the signal region are smooth. they can not contribute peaking in  $M(p\bar{p})$  signal region, they are not affect the estimate of the signal. These background shapes can be described using third order chebyshev polynomials.

# Fitting

The line-shape of  $\chi_{cJ}$ :

$$(E_\gamma^3 \times \text{Mcshape} \times f_{\text{damp}}(E_\gamma)) \otimes \text{Gaussian}(\delta m, \sigma)$$

These background shapes : using third order chebyshev

Considering the resolution of the detector , we use Mcshape to describe the signal. And modified by a factor  $E_\gamma^3$  ( $E_\gamma$ :the energy of the transition photon ), but leads to a diverging tail at lower energies

To damp the  $E_\gamma^3$ , an additional factor of  $f_{\text{damp}} = \exp(-\frac{E_r^2}{8\beta^2})$   $\beta = 0.273\text{GeV}$

is added (which is used by CLEO\_c, it is an empirical equation)

The gauss represent the possible difference in the invariant mass resolution between data and mc

Parameters of smearing Gaussian for  $\chi_{cJ}$  are float.

The chi2/ndf : 1.47

|             | $\epsilon$ (%) | N             | B ( $\chi_{cJ} \rightarrow p\bar{p}$ ) ( $10^{-5}$ ) |

PhysRevLett. 102. 011801

Fits to the resulting photon-energy spectrum

A fit using a relativistic Breit-Wigner distribution modified by a factor of  $E_\gamma^3$  improves the fit around the peak but leads to a diverging tail at higher energies. To damp the  $E_\gamma^3$ , an additional factor of  $\exp\left(-\frac{E_\gamma^2}{8\beta^2}\right)$  with  $\beta = 0.273\text{GeV}$  is added.
