Outline

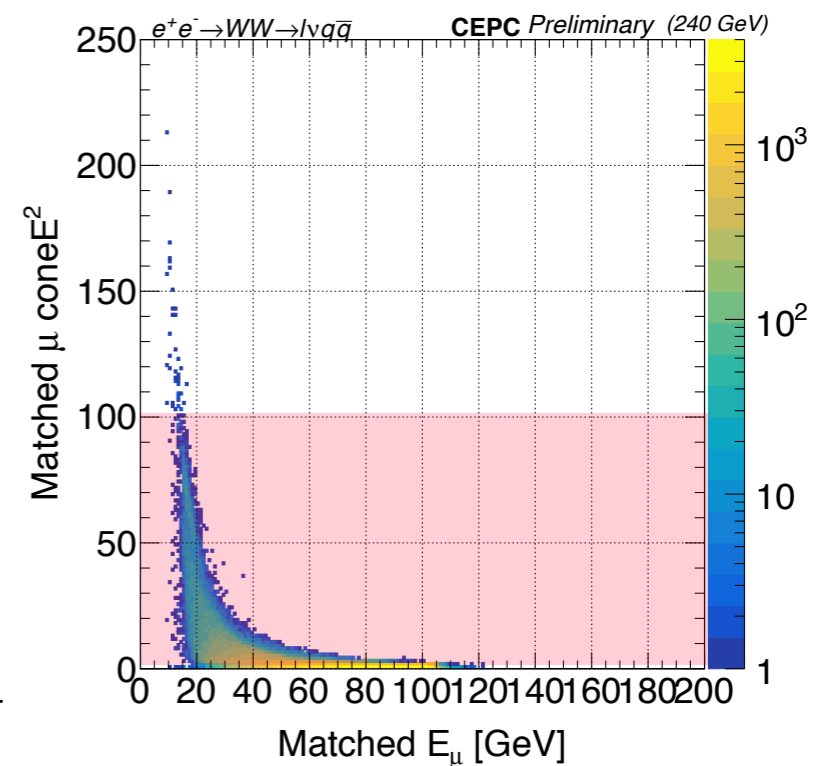

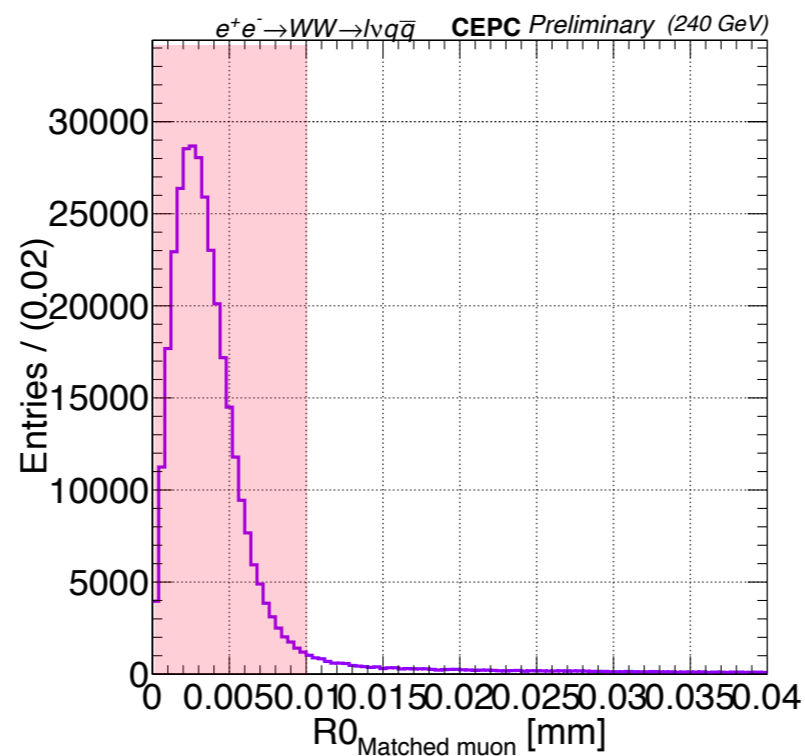

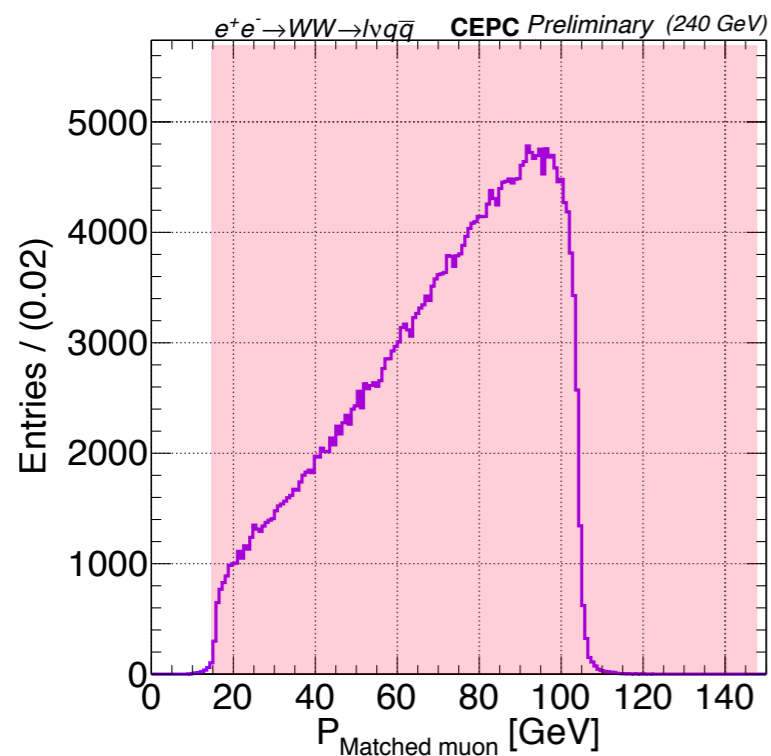

- **The veto criteria for prompt muon before jet clustering.**
- **Follow the ALEPH's paper to do the event selections.**

- In order to veto the prompt muon in WW to $\mu\nu q\bar{q}$, there is a code called “ISOLatedLeptonFinderProcessor” before putting PFOs into the jet clustering algorithm.
- The veto criteria are as following(should satisfy all of them at the same time)
 - Pass μ ID (from Arbor)
 - $R0 < 0.01$ mm
 - Track energy > 30 GeV
 - Apply ISOLatedPolynomial decision

$coneE = \text{Energy in the Cone(excepts the muon)} / \text{Energy of muon}$

ISOLatedPolynomial: $(coneE)^2 \leq 20E_{\mu} - 300$

■ These plots are done by the matched muon(prompt) muon.

■ After studying these veto criteria, I made some changes(in read).

- Pass μ ID (from Arbor)
- $R0 < 0.01$ mm
- **Track energy > 15 GeV**
- **Apply ISOLatedPolynomial decision**

■ If there are more than two muons pass through these selection, I will pick up the most energetic muon.

■ I will do more detail study for the polynomial way.

ISOLatedPolynomial: $(coneE)^2 \leq 100$

Select the Final State($\mu\nu q\bar{q}$) in V4

V4	# of event	Efficiency
Tot # of event	383227	—
> 7 Tracks	383227	100%
$E_{\text{Miss}} \& P_{\text{Miss}} > 35 \text{ GeV}$	254242	66%
Select the μ	206939	54%
Detector acceptance $ \cos(\theta_{\mu}) < 0.995$	206939	54%

- I followed the ALEPH paper to do these selections(track, missing energy and momentum).
- “Select the μ ” is used the selections in S4.
